Inheritance
Dec. 1, Ch 15.1-15.2
Announcements

Homework 8 due tomorrow
Highlights

- Creating parent/child classes (inheritance)

class Parent{
    public:
    void foo();
};

class Child : public Parent {
    public:
    Child();
};
Story time

A long time ago in a galaxy far, far away....
Story time

- Large ears
- Eyes with vertical pupils
- Sensory whiskers
- Soft fur
- Retractable claws and padded feet
- Tail

I ARE DUNECAT

I CONTROLS THE SPICE,
I CONTROLS THE UNIVERSE.

DUNE CAT
haz no fear, fear iz mindkillerz
Derived classes

Let's make this story into code!

To create a child class from a parent class, use a : in the (child) class declaration

```cpp
class Dunecat : public ArrakianSandworm {
public:
    Dunecat();
};
```

(See: dunecat.cpp)
Derived classes

In a parent/child class relationship, the child gets all variables and functions of the parent.

This allows you to build off previous work, even if you need to modify it slightly.

This also makes it easier to maintain code, as changing it in the parent class can effect all children (and the children's children).
Derived classes

Typically you use classes when you have multiple objects that are somewhat similar.

You group the similar parts into a parent class and the different parts into children classes.

For examples all chairs have a flat surface to sit on, but they come in different designs (folding types that you are sitting on) (or rolling types).
Derived classes

Parent: (Internal combustion engine)

Children:
### Slime Devil

- **Medium immortal humanoid (devil, ooze)**
- **HP**: 123; Bloodied 61
- **AC**: 30, Fortitude 28, Reflex 29, Will 28
- **Speed**: 6, swim 6
- **Resist**: 20 acid

**Traits**
- **Mycelial Body**: The slime devil ignores difficult terrain and does not provoke opportunity attacks by moving.

**Standard Actions**
- **Caustic Slam (acid)**: At-Will
  - **Attack**: Melee 1 (one creature); +19 vs. Fortitude
  - **Hit**: 3d8 + 11 acid damage.
- **Diabolical Engulfment (acid)**: At-Will
  - **Attack**: Melee 1 (one Medium or smaller enemy); +19 vs. Reflex
  - **Hit**: The devil grabs the target and shifts 1 square into the target's square. Until the grab ends, the target is dazed and takes ongoing 10 acid damage. While the devil has the target grabbed, attacks against the devil deal half damage to it and half damage to the grabbed creature. When the devil moves, it pulls the target with it. In addition, the target remains grabbed, and the devil does not provoke an opportunity attack from the target.

### Level 16 Lurker

- **XP**: 1,400

### Herald of Colorless Fire

- **Medium natural animate (construct, fire)**
- **HP**: 244; Bloodied 122
- **AC**: 41, Fortitude 37, Reflex 40, Will 37
- **Speed**: 8, fly 6
- **Resist**: 15 fire

**Traits**
- **Frozen in Place**: Whenever the herald of colorless fire takes cold damage, it cannot use flickering flame until the end of its next turn.

**Standard Actions**
- **Caress of Flame (fire, force)**: At-Will
  - **Attack**: Melee 1 (one creature); +32 vs. AC
  - **Hit**: 3d10 + 19 fire and force damage.
- **Storm of Colorless Fire (fire, force)**: Recharge
  - **Effect**: The herald makes the following attack twice, shifting half its speed between the attacks. The herald cannot target the same creature with both attacks.
  - **Attack**: Close burst 1 (creatures in burst); +30 vs. Reflex
  - **Hit**: 4d10 + 16 fire and force damage, and ongoing 15 fire damage (save ends).
Phone
What type of object is a Dunecat?

It is (obviously) a Dunecat, but could it also be classified as an ArrakianSandworm? In fact, yes... both of these are legal:

```cpp
Dunecat kitty;
ArrakianSandworm wormmy = kitty;
```

Dunecats have more functionality than ArrakianSandworms, so they can act as one (See: dunecatTypes.cpp)
Constructors + inheritance

Constructors need to be run every time you make an object...

Now that objects have multiple types what constructors are being run?

Both actually (again)

(See: dunecatConstructors.cpp)
Constructors + inheritance

If you do not specify what constructor to use, it will use the default constructor (or give an error if this does not exist)

You can also specify a non-default constructor by using a “:” after the child's constructor

```cpp
Dunecat::Dunecat() : ArrakianSandworm("kitty")
{
    //name = "kitty";
}
```
We know about two scopes for variables:
1. public (anyone, anywhere can use)
2. private (only my class can use)

But there is a third:
3. protected (me or my children can use)

If you think your children will modify/use a variable, make it protected
(See: classScopes.cpp)
protected

While children technically inherit the private variables/functions, they cannot use them.

So effectively, they do not inherit these.

It is not considered bad practice to make variables protected (unlike public).

Does access matter?
Yes, because computer viruses.
Redefine functions

As children add functionality to a parent class, they may want to redefine some functions.

This is different than overloading, where you create multiple versions with the same name.

When you redefine, you are basically replacing an old function with a new version.

(See: computers.cpp)
Redefine functions

After you have redefined a function, the default name will go to the child's version. However, you can still access the parent's version by using "::" (class affiliation).

```cpp
Laptop rightHere = Laptop("2.7 GHz i5", "8 GB DDR3", 3);
rightHere.displaySpecs();
// runs Laptop's version of displaySpecs
rightHere. Computer:: displaySpecs();
// runs Computer's version of displaySpecs
```
As we saw before, constructors are not really inherited (though they are called)

overloading operators will also not be inherited (as computer cannot convert parent into child class)

Deconstructors are also not inherited, but the parent's version of the deconstructor will always run (See: childDeconstructor.cpp)
