# The QR algorithm

The most common method for solving small (dense) eigenvalue problems. The basic algorithm:

#### QR without shifts

- 1. Until Convergence Do:
- 2. Compute the QR factorization A=QR
- 3. Set A := RQ
- 4. EndDo
- ightharpoonup "Until Convergence" means "Until A becomes close enough to an upper triangular matrix"

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-

- Above basic algorithm is never used as is in practice. Two variations:
- (1) Use shift of origin and
- (2) Start by transforming A into an Hessenberg matrix

- ightharpoonup Note:  $A_{new}=RQ=Q^H(QR)Q=Q^HAQ$
- $lacksquare A_{new}$  is similar to A throughout the algorithm .
- ightharpoonup Convergence analysis complicated but insight: we are implicitly doing a QR factorization of  $A^k$ :

QR-Factorize: Multiply backward:

Step 1 
$$A_0 = Q_0 R_0$$
  $A_1 = R_0 Q_0$   
Step 2  $A_1 = Q_1 R_1$   $A_2 = R_1 Q_1$ 

Step 2 
$$A_1=Q_1R_1 \qquad A_2=R_1Q_1$$
  
Step 3:  $A_2=Q_2R_2 \qquad A_3=R_2Q_2$  Then:

$$\begin{aligned} [Q_0Q_1Q_2][R_2R_1R_0] &= Q_0Q_1A_2R_1R_0 \\ &= Q_0Q_1R_1Q_1R_1R_0 \\ &= \underbrace{(Q_0R_0)}_{A}\underbrace{(Q_0R_0)}_{A}\underbrace{(Q_0R_0)}_{A} = A^3 \end{aligned}$$

 $ightharpoonup [Q_0Q_1Q_2][R_2R_1R_0] == \mathsf{QR}$  factorization of  $A^3$ 

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-9

# $Practical\ QR\ algorithms:\ Shifts\ of\ origin$

Observation: (from theory): Last row converges fastest. Convergence is dictated by  $\frac{|\lambda_n|}{|\lambda_{n-1}|}$ 

- We will now consider only the real symmetric case.
- Eigenvalues are real.
- $ightharpoonup A^{(k)}$  remains symmetric throughout process.
- As k goes to infinity the last column and row (except  $a_{nn}^{(k)}$ ) converge to zero quickly.,,
- ightharpoonup and  $a_{nn}^{(k)}$  converges to lowest eigenvalue.

$$A^{(k)} = egin{pmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & a \ \cdot & \cdot & \cdot & \cdot & \cdot & a \ \cdot & \cdot & \cdot & \cdot & \cdot & a \ \cdot & \cdot & \cdot & \cdot & \cdot & a \ \hline a & a & a & a & a & a \end{pmatrix}$$

ightharpoonup Idea: Apply QR algorithm to  $A^{(k)} - \mu I$  with  $\mu = a_{nn}^{(k)}$ . Note: eigenvalues of  $A^{(k)} - \mu I$  are shifted by  $\mu$ , and eigenvectors are the same.

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 - Eigen2New

QR with shifts

- 1. Until row  $a_{in}$ ,  $1 \le i < n$  converges to zero DO:
- 2. Obtain next shift (e.g.  $\mu = a_{nn}$ )
- 3.  $A \mu I = QR$
- 5. Set  $A := RQ + \mu I$
- 6. EndDo
- Convergence (of last row) is cubic at the limit! [for symmetric case

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 - Eigen2New

Result of algorithm:

$$A^{(k)} = egin{pmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & 0 \ \cdot & \cdot & \cdot & \cdot & \cdot & 0 \ \cdot & \cdot & \cdot & \cdot & \cdot & 0 \ \cdot & \cdot & \cdot & \cdot & \cdot & 0 \ \cdot & \cdot & \cdot & \cdot & \cdot & 0 \ \hline 0 & 0 & 0 & 0 & 0 & \lambda_n \end{pmatrix}$$

Next step: deflate, i.e., apply above algorithm to  $(n-1) \times$ (n-1) upper triangular matrix.

# Practical algorithm: Use the Hessenberg Form

Recall: Upper Hessenberg matrix is such that

$$a_{ij} = 0$$
 for  $j < i - 1$ 

Observation: The QR algorithm preserves Hessenberg form (tridiagonal form in symmetric case). Results in substantial savings.

Transformation to Hessenberg form

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 - Eigen2New

- Choose a w in  $H_1=I-2ww^T$  to make the first column have zeros from position 3 to n. So  $w_1 = 0$ .
- $\triangleright$  Apply to left:  $B = H_1A$
- Apply to right:  $A_1 = BH_1$ .

Main observation: the Householder matrix  $H_1$  which transforms the column A(2:n,1) into  $e_1$  works only on rows 2 to n. When applying the transpose  $H_1$  to the right of  $B = H_1 A$ , we observe that only columns 2 to n will be altered. So the first column will retain the desired pattern (zeros below row 2).

Algorithm continues the same way for columns 2, ..., n-2.

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 - Eigen2New

- 1. Choose  $G_1 = G(1, 2, \theta_1)$  so that  $(G_1^T A_0)_{21} = 0$
- 2. Choose  $G_2 = G(2, 3, \theta_2)$  so that  $(G_2^T A_1)_{31} = 0$

### QR for Hessenberg matrices

➤ Need the "Implicit Q theorem"

Suppose that  $Q^TAQ$  is an unreduced upper Hessenberg matrix. Then columns 2 to n of Q are determined uniquely (up to signs) by the first column of Q.

 $\blacktriangleright$  In other words if  $V^TAV = G$  and  $Q^TAQ = H$  are both Hessenberg and V(:,1)=Q(:,1) then  $V(:,i)=\pm Q(:,i)$  for i = 2 : n.

Implication: To compute  $A_{i+1} = Q_i^T A Q_i$  we can:

- ightharpoonup Compute 1st column of  $Q_i$  [== scalar imes A(:,1)]
- $\triangleright$  Choose other columns so  $Q_i$  = unitary, and  $A_{i+1}$  = Hessenberg.

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

$$lackbrack A_2 = G_2^T A_1 G_2 = egin{pmatrix} * & * & * & * & * \ * & * & * & * & * \ 0 & * & * & * & * \ 0 & + & * & * & * \ 0 & 0 & 0 & * & * \end{pmatrix}$$

3. Choose  $G_3 = G(3,4,\theta_3)$  so that  $(G_3^T A_2)_{42} = 0$ 

$$lackbox{ } lackbox{ } A_3 = G_3^T A_2 G_3 = egin{pmatrix} * & * & * & * & * \ * & * & * & * & * \ 0 & * & * & * & * \ 0 & 0 & * & * & * \ 0 & 0 & + & * & * \end{pmatrix}$$

4. Choose  $G_4 = G(4, 5, \theta_4)$  so that  $(G_4^T A_3)_{53} = 0$ 

13-11

13-12

- Process known as "Bulge chasing"
- > Similar idea for the symmetric (tridiagonal) case

13-13 TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-13

# The min-max theorem (Courant-Fischer)

Label eigenvalues decreasingly:

$$\lambda_1 > \lambda_2 > \cdots > \lambda_n$$

The eigenvalues of a Hermitian matrix  $oldsymbol{A}$  are characterized by the relation

$$oldsymbol{\lambda}_k = \max_{S, \; \dim(S) = k} \;\; \, \min_{x \in S, x 
eq 0} \; \, rac{(Ax, x)}{(x, x)}$$

**Proof:** Preparation: Since A is symmetric real (or Hermitian complex) there is an orthonormal basis of eigenvectors  $u_1,u_2,\cdots,u_n$ . Express any vector x in this basis as  $x=\sum_{i=1}^n \alpha_i u_i$ . Then :  $(Ax,x)/(x,x)=[\sum \lambda_i |\alpha_i|^2]/[\sum |\alpha_i|^2]$ .

(a) Let S be any subspace of dimension k and let  $\mathcal{W}=\mathrm{span}\{u_k,u_{k+1},\cdots,u_n\}$ . A dimension argument (used before) shows that  $S\cap\mathcal{W}\neq\{0\}$ . So there is a

# The symmetric eigenvalue problem: Basic facts

 $\triangleright$  Consider the Schur form of a real symmetric matrix A:

$$A = QRQ^H$$

Since  $A^H = A$  then  $R = R^H >$ 

Eigenvalues of  $oldsymbol{A}$  are real

and

There is an orthonormal basis of eigenvectors of  $oldsymbol{A}$ 

In addition, Q can be taken to be real when A is real.

$$(A - \lambda I)(u + iv) = 0 \rightarrow (A - \lambda I)u = 0 \& (A - \lambda I)v = 0$$

ightharpoonup Can select eigenvector to be either  $oldsymbol{u}$  or  $oldsymbol{v}$ 

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-14

non-zero  $x_w$  in  $S\cap \mathcal{W}$ . Express this  $x_w$  in the eigenbasis as  $x_w=\sum_{i=k}^n \alpha_i u_i$ . Then since  $\lambda_i \leq \lambda_k$  for  $i\geq k$  we have:

$$rac{(Ax_w,x_w)}{(x_w,x_w)} = rac{\sum_{i=k}^n \lambda_i |lpha_i|^2}{\sum_{i=k}^n |lpha_i|^2} \leq \lambda_k$$

So for any subspace S of dim. k we have  $\min_{x \in S, x \neq 0} (Ax, x)/(x, x) \leq \lambda_k$ .

(b) We now take  $S_*=\mathrm{span}\{u_1,u_2,\cdots,u_k\}$ . Since  $\lambda_i\geq \lambda_k$  for  $i\leq k$ , for this particular subspace we have:

$$\min_{x \;\in\; S_*,\; x 
eq 0} rac{(Ax,x)}{(x,x)} = \min_{x \;\in\; S_*,\; x 
eq 0} rac{\sum_{i=1}^k \lambda_i |lpha_i|^2}{\sum_{i=k}^n |lpha_i|^2} = \lambda_k.$$

(c) The results of (a) and (b) imply that the max over all subspaces S of dim. k of  $\min_{x \in S, x \neq 0} (Ax, x)/(x, x)$  is equal to  $\lambda_k$ 

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-15

➤ Consequences:

$$\lambda_1 = \max_{x 
eq 0} rac{(Ax,x)}{(x,x)} \hspace{0.5cm} \lambda_n = \min_{x 
eq 0} rac{(Ax,x)}{(x,x)}$$

Actually 4 versions of the same theorem. 2nd version:

$$oldsymbol{\lambda}_k = \min_{S, \; \dim(S) = n-k+1} \quad \max_{x \in S, x 
eq 0} \; rac{(Ax,x)}{(x,x)}$$

- ➤ Other 2 versions come from ordering eigenvalues increasingly instead of decreasingly.
- Write down all 4 versions of the theorem
- Use the min-max theorem to show that  $\|A\|_2 = \sigma_1(A)$  the largest singular value of A.

13-17 TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-17

Interlacing Theorem: Denote the  $k \times k$  principal submatrix of A as  $A_k$ , with eigenvalues  $\{\lambda_i^{[k]}\}_{i=1}^k$ . Then

$$oldsymbol{\lambda}_1^{[k]} \geq oldsymbol{\lambda}_1^{[k-1]} \geq oldsymbol{\lambda}_2^{[k]} \geq \lambda_2^{[k-1]} \geq \dots oldsymbol{\lambda}_{k-1}^{[k]} \geq oldsymbol{\lambda}_k^{[k]}$$

**Example:**  $\lambda_i$ 's = eigenvalues of A,  $\mu_i$ 's = eigenvalues of  $A_{n-1}$ :

- Many uses.
- ➤ For example: interlacing theorem for roots of orthogonal polynomials

3-18 TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-18

### The Law of inertia

Inertia of a matrix = [m, z, p] with m = number of < 0 eigenvalues, z = number of zero eigenvalues, and p = number of > 0 eigenvalues.

Sylvester's Law of inertia: If  $X \in \mathbb{R}^{n \times n}$  is nonsingular, then A and  $X^TAX$  have the same inertia.

- Suppose that  $A = LDL^T$  where L is unit lower triangular, and D diagonal. How many negative eigenvalues does A have?
- Assume that A is tridiagonal. How many operations are required to determine the number of negative eigenvalues of A?

Devise an algorithm based on the inertia theorem to compute the i-th eigenvalue of a tridiagonal matrix.

What is the inertia of the matrix

$$egin{pmatrix} I & F \ F^T & 0 \end{pmatrix}$$

where F is  $m \times n$ , with n < m, and of full rank?

[Hint: use a block LU factorization]

### Bisection algorithm for tridiagonal matrices:

- $\triangleright$  Goal: to compute i-th eigenvalue of A (tridiagonal)
- Get interval [a,b] containing  $a \le \lambda_n \le \cdots \le \lambda_1 \le b$  spectrum [Gershgorin]:
- ightharpoonup Let  $\sigma=(a+b)/2=$  middle of interval
- ightharpoonup Calculate p= number of positive eigenvalues of  $A-\sigma I$
- ullet If  $p \geq i$  then  $\lambda_i \in \ (oldsymbol{\sigma},\ b] 
  ightarrow \ ext{set} \ oldsymbol{a} := oldsymbol{\sigma}$

- ullet Else then  $\lambda_i \in [a, \ \sigma] 
  ightarrow \ ext{set} \ ullet b := oldsymbol{\sigma}$
- ightharpoonup Repeat until b-a is small enough.

13-21 TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-21

### The QR algorithm for symmetric matrices

- Most important method used: reduce to tridiagonal form and apply the QR algorithm with shifts.
- ➤ Householder transformation to Hessenberg form yields a tridiagonal matrix because

$$HAH^T = A_1$$

is symmetric and also of Hessenberg form  $\triangleright$  it is tridiagonal symmetric.

Tridiagonal form preserved by QR similarity transformation

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 - Eigen2New

13-22

## Practical method

- ➤ How to implement the QR algorithm with shifts?
- ➤ It is best to use Givens rotations can do a shifted QR step without explicitly shifting the matrix.
- ➤ Two most popular shifts:

 $s=a_{nn}$  and s= smallest e.v. of A(n-1:n,n-1:n)

# ${\it Jacobi\ iteration\ -\ Symmetric\ matrices}$

➤ Main idea: Rotation matrices of the form

$$J(p,q, heta) = egin{pmatrix} 1 & \dots & 0 & & \dots & 0 & 0 \ dots & \ddots & dots &$$

 $c=\cos heta$  and  $s=\sin heta$  are so that  $J(p,q, heta)^TAJ(p,q, heta)$  has a zero in position (p,q) (and also (q,p))

➤ Frobenius norm of matrix is preserved – but diagonal elements become larger ➤ convergence to a diagonal.

TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

- $\blacktriangleright$  Let  $B = J^T A J$  (where  $J \equiv J_{p,q,\theta}$ ).
- $\blacktriangleright$  Look at  $2 \times 2$  matrix B([p,q],[p,q]) (matlab notation)
- lacksquare Keep in mind that  $a_{pq}=a_{qp}$  and  $b_{pq}=b_{qp}$

$$egin{pmatrix} \left(egin{array}{c} b_{pp} & b_{pq} \ b_{qp} & b_{qq} \end{array}
ight) &= \left(egin{array}{c} c & -s \ s & c \end{array}
ight) \left(egin{array}{c} a_{pp} & a_{pq} \ a_{qp} & a_{qq} \end{array}
ight) \left(egin{array}{c} c & s \ -s & c \end{array}
ight) \ &= \left(egin{array}{c} c & -s \ s & c \end{array}
ight) \left[egin{array}{c} ca_{pp} - sa_{pq} & sa_{pp} + ca_{pq} \ ca_{qp} - sa_{qq} & sa_{pq} + ca_{qq} \end{array}
ight] \ &= \left(egin{array}{c} ca_{pp} - sa_{qq} & sa_{pq} + ca_{qq} \end{array}
ight]$$

$$\left\lceil \frac{c^2 a_{pp} + s^2 a_{qq} - 2sc \; a_{pq} \left| (c^2 - s^2) a_{pq} - sc (a_{qq} - a_{pp})}{*} \right| \\ \frac{c^2 a_{qq} + s^2 a_{pp} + 2sc \; a_{pq}}{*} \right|$$

- ightharpoonup Want:  $(c^2-s^2)a_{pq}-sc(a_{qq}-a_{pp})=0$
- TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 Eigen2New

13-25

- Define:  $A_O = A \mathsf{Diag}(A)$   $\equiv A$  'with its diagonal entries replaced by zeros'
- ▶ Observations: (1) Unitary transformations preserve  $\|.\|_F$ . (2) Only changes are in rows and columns p and q.
- $\blacktriangleright$  Let  $B=J^TAJ$  (where  $J\equiv J_{p,q, heta}$ ). Then,

$$a_{pp}^2 + a_{qq}^2 + 2a_{pq}^2 = b_{pp}^2 + b_{qq}^2 + 2b_{pq}^2 = b_{pp}^2 + b_{qq}^2$$

because  $b_{pq}=0$ . Then, a little calculation leads to:

$$egin{aligned} \|B_O\|_F^2 &= \|B\|_F^2 - \sum b_{ii}^2 = \|A\|_F^2 - \sum b_{ii}^2 \ &= \|A\|_F^2 - \sum a_{ii}^2 + \sum a_{ii}^2 - \sum b_{ii}^2 \ &= \|A_O\|_F^2 + (a_{pp}^2 + a_{qq}^2 - b_{pp}^2 - b_{qq}^2) \ &= \|A_O\|_F^2 - 2a_{pq}^2 \end{aligned}$$

7 \_\_\_\_\_\_ TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

$$rac{c^2-s^2}{2sc}=rac{a_{qq}-a_{pp}}{2a_{pq}}\equiv au$$

 $\blacktriangleright$  Letting  $t = s/c \ (= \tan \theta) \rightarrow \text{quad. equation}$ 

$$t^2 + 2\tau t - 1 = 0$$

- $ightharpoonup t = -\tau \pm \sqrt{1 + \tau^2} = \frac{1}{\tau + \sqrt{1 + \tau^2}}$
- $\blacktriangleright$  Select sign to get a smaller t so  $\theta \leq \pi/4$ .
- Then:  $c=\frac{1}{\sqrt{1+t^2}}; \quad s=c*t$
- Implemented in matlab script jacrot(A,p,q) See HW6.

.26 TB: 28-30; AB: 1.3.3, 3.2.3, 3.4.2, 3.5, 3.6.2; GvL 8.1-8.2.3 – Eigen2New

13-26

- $ightharpoonup \|A_O\|_F$  will decrease from one step to the next.
- $begin{aligned} lacksquare \end{aligned} ext{Let } \|A_O\|_I = \max_{i \neq j} |a_{ij}|. ext{ Show that } \end{aligned}$

$$\|A_O\|_F \le \sqrt{n(n-1)} \|A_O\|_I$$

Use this to show convergence in the case when largest entry is zeroed at each step.
