# Constraint sat. prob. (Ch. 6)

Announcements

Writing 3 due next week
   -Find papers for project
   -scholar.google.com is your friend!

I suggest not looking for your problem
(e.g. if you want to do "poker" as your project,
do not google search "poker research")
… instead look at the technique used
(if you plan to solve "poker" using minimax,
search for general "minimax" papers)

CSP

A <u>constraint satisfaction problem</u> is when there are a number of variables in a domain with some restrictions

A <u>consistent</u> assignment of variables has no violated constraints

A <u>complete</u> assignment of variables has no unassigned variables
   (A solution is complete and consistent)

CSP

Map coloring is a famous CSP problem
Variables: each state/country
Domain: {yellow, blue, green, purple} (here)
Constraints: No adjacent variables same color

Map Coloring Problem

Can you finish coloring the map using only these four colors?

www.squidoo.com/50-states

Consistent but partial

CSP

partial and
not consistent

Consistent and
complete

CSP

Another common use of CSP is job scheduling

10X10 Job Shop Scheduling Problem
Constrained Schedule

CSP

Suppose we have 3 jobs: J_1, J_2, J_3

If J_1 takes 20 time units to complete, J_2 takes 30 and J_3 takes 15 <u>but</u> J_1 must be done before J_3 (jobs cannot happen at the same time)

How to write this as a boolean expression?

CSP

Suppose we have 3 jobs: J_1, J_2, J_3

If J_1 takes 20 time units to complete, J_2 takes 30 and J_3 takes 15 <u>but</u> J_1 must be done before J_3

We can represent this as (**<u>and</u>** them together):

J_1 & J_2: ($J_1 + 20 \leq J_2$ **<u>or</u>** $J_2 + 30 \leq J_1$)

J_1 & J_3: ($J_1 + 20 \leq J_3$)

J_2 & J_3: ($J_2 + 30 \leq J_3$ **<u>or</u>** $J_3 + 15 \leq J_2$)

Types of constraints

A <u>unary</u> constraint is for a single variable (i.e. J_1 cannot start before time 5)

<u>Binary</u> constraints are between two variables (i.e. J_1 starts before J_2)

Constraints can involve more variables, such as in Sudoku all numbers on a row needs to be different: AllDiff(a11,a12,a13,a14, …)

Types of constraints

All constraints can be reduced to just binary and unary constraints, but may require making variables to store temporary information

Our goal is to use the constraints to narrow the domains of possible values of variables

k-consistency is a measurement of how well the domains satisfy different degrees of the constraints (larger 'k' = satisfy more complex)

Types of constraints

K-consistency is:
For any consistent sets size (k-1), there exists a valid value for any other variable (not in set)

1-consistency: All values in the domain satisfy the variable's unary constraints
2-consistency: All binary values are in domain
3-consistency: Given consistent 2 variables, there is a value for a third variable(i.e. if {A,B} is consistent, then exists C s.t. {A,C}&{B,C})

Types of constraints

For example, 1-consistent means you can pick 0 consistent variables (if you pick nothing it is always consistent) then any assignment to a new variable is also consistent

This boils down to saying you can pick any valid pick of a single variable in isolation

In other words, you satisfy the unary constraints

Types of constraints

2-consistent means you pick a valid value from the domain for one variable and see if there is <u>any</u> valid assignment for a second var
3-consistent means you pick a valid pair of values for 2 variables and see if there is <u>any</u> valid assignment for a third variable

If you are unable to find a valid assignment for the last variable, it is not consistent

Types of constraints

Rules: 1. Tasmania cannot be red
2.Neighboring providences cannot share colors

2 Colors:
red
green

Types of constraints

WA = {red, green}
NT = {red, green}
Q = {red, green}
SA = {red, green}
NSW = {red, green}
V = {red, green}
T = {red, green}

Not 1-consistent as we need T to not be red
(i.e. rule #2 eliminates T=red)

Types of constraints

WA = NT = Q = SA = NSW = V
= {red, green}
T = {green}

1-consistent now

Also 2-consistent, for example:
Pick WA as "set k-1", then try to pick NT...
If WA=green, then we can make NT=red
if WA=red, NT=green (true for all pairs)

Types of constraints

WA = NT = Q = SA = NSW = V
= {red, green}
T = {green}

Not 3-consistent!

Pick (WA, SA) and add NT... If NT=green, will not work with either: (WA=red,SA=green) or (WA=green,SA=red)... NT=red also will not work, so NT's domain is empty and not 3-cons.

Types of constraints

Try to do k-consistency for this job problem
(Domains for all: {1, 2, 3, 4, 5, 6, 7, 8...})
Jobs cannot overlap
J3 takes 3 time units
J2 takes 2 time units
J1 takes 1 time unit
J1 must happen before J3
J2 cannot happen at time 1
All jobs must finish by time 7
(i.e. you can start J2 at time 5 but not at time 6)

Applying constraints

We can repeatedly apply our constraint rules to shrink the domain of variables (we just shrunk NT's domain to nothing)

This reduces the size of the domain, making it easier to check:
- If the domain size is zero, there are no solutions for this problem
- If the domain size is one, this variable must take on that value (the only one in domain)

Applying constraints

AC-3 checks all 2-consistency constraints:

1. Add all binary constraints to queue
2. Pick a binary constraint (X_i, Y_j) from queue
3. If x in domain(X_i) and no consistent y in domain(Y_j), then remove x from domain(X_i)
4. If you removed in step 3, update all other binary constraints involving X_i (i.e. (X_i, X_k))
5. Goto step 2 until queue empty
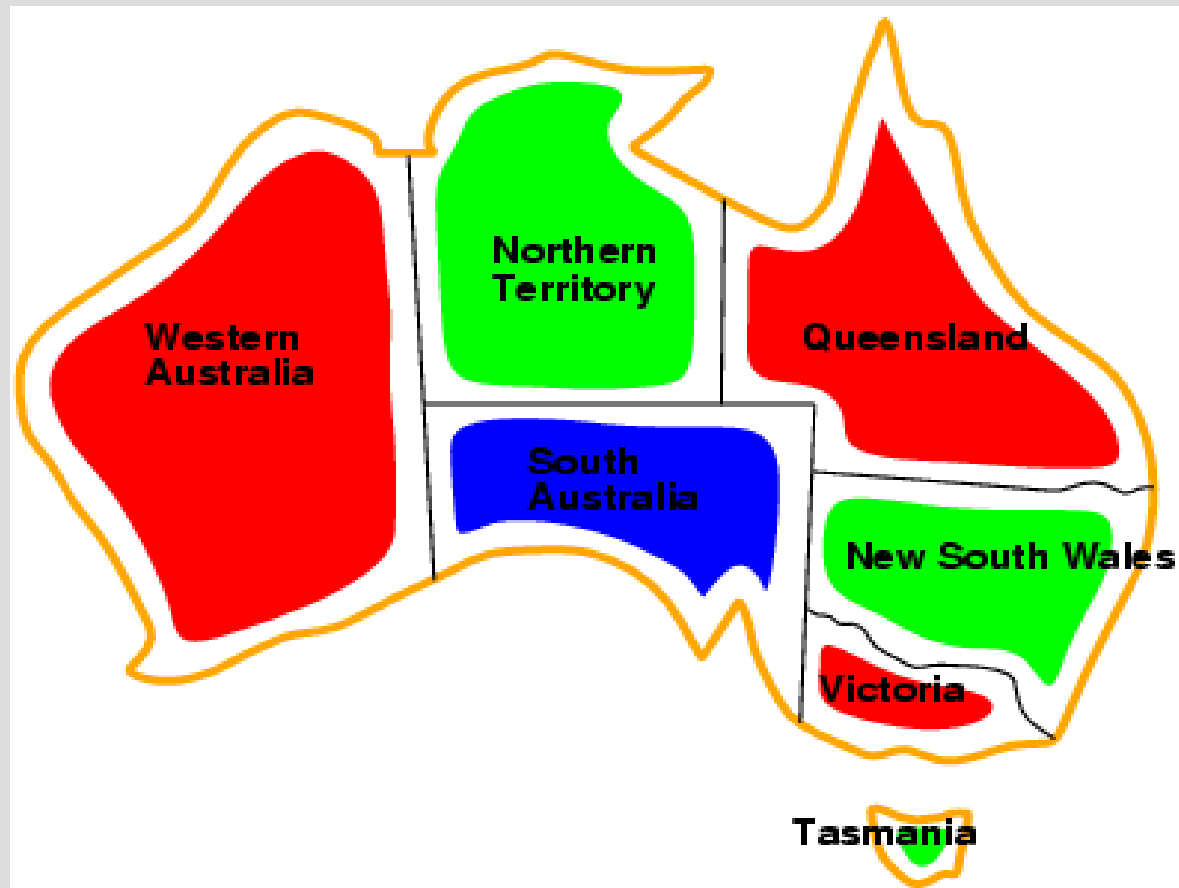

Applying constraints

Some problems can be solved by applying constraint restrictions (such as sudoku)
(i.e. the size of domain is one after reduction)

Harder problems this is insufficient and we will need to search to find a solution

Which is what we will do... now

CSP vs. search

Let us go back to Australia coloring:

How can you color using search techniques?

CSP vs. search

We can use an incremental approach:

State = currently colored provinces (and their color choices)

Action = add a new color to any province that does not conflict with the constraints

Goal: To find a state where all provinces are colored

CSP vs. search

Is there a problem?

CSP vs. search

Is there a problem?

Let d = domain size (number of colorings), n = number of variables (provinces)

The number of leaves are $n! * d^n$

However, there are only d^n possible states in the CSP so there must be a lot of duplicate leaves (not including mid-tree parts)

CSP vs. search

CSP assumes one thing general search does not: the order of actions does not matter

In CSP, we can assign a value to a variable at any time and in any order without changing the problem (all we care about is the end state)

So all we need to do is limit our search to one variable per depth, and we will have a match with CSP of d^n leaves (all combinations)
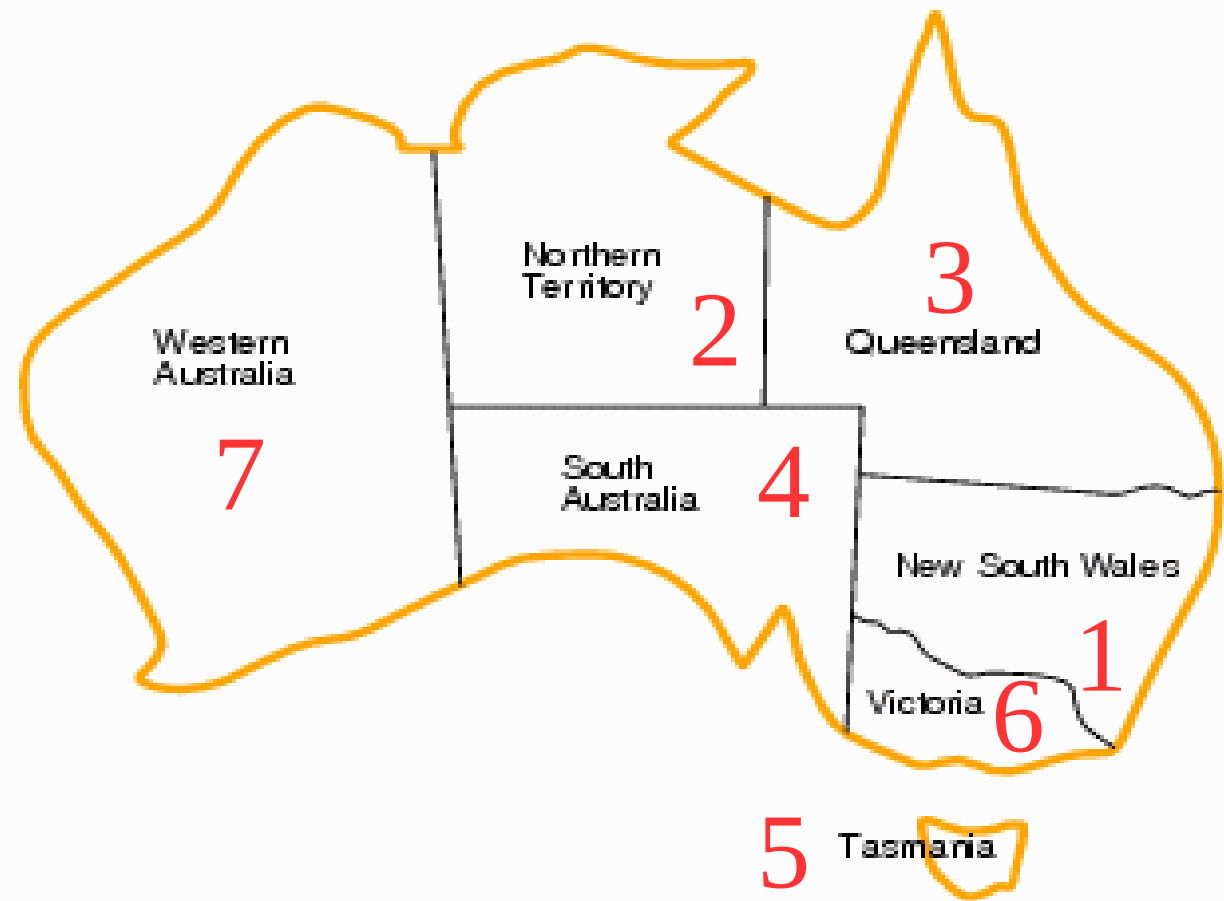

CSP vs. search

Let's apply CSP modified DFS on Australia:
(assign values&variables in alphabetical order)

1st: blue
2nd: green
3rd: red

CSP vs. search

CSP vs. search

STOP PICKING BLUE EVERY TIME!!!!
