LINEAR MAPPINGS [1.8]
A transformation or function or mapping from $\mathbb{R}^n$ to $\mathbb{R}^m$ is a rule which assigns to every $x$ in $\mathbb{R}^n$ a vector $T(x)$ in $\mathbb{R}^m$.

$\mathbb{R}^n$ is called the domain space of $T$ and $\mathbb{R}^m$ the image space or co-domain of $T$.

Notation:

$$T : \mathbb{R}^n \rightarrow \mathbb{R}^m$$

$T(x)$ is the image of $x$ under $T$.
Example: Take the mapping from \( \mathbb{R}^2 \) to \( \mathbb{R}^3 \):

\[
T: \mathbb{R}^2 \quad \longrightarrow \quad \mathbb{R}^3
\]

\[
x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \longrightarrow T(x) = \begin{pmatrix} x_1 + x_2 \\ x_1 x_2 \\ x_1^2 + x_2^2 \end{pmatrix}
\]

Example: Another mapping from \( \mathbb{R}^2 \) to \( \mathbb{R}^3 \):

\[
T: \mathbb{R}^2 \quad \longrightarrow \quad \mathbb{R}^3
\]

\[
x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \longrightarrow T(x) = \begin{pmatrix} x_1 + x_2 \\ x_1 - x_2 \\ x_1 + 5x_2 \end{pmatrix}
\]

What is the main difference between these 2 examples?
**Definition** A mapping $T$ is **linear** if:

(i) $T(u + v) = T(u) + T(v)$ for $u, v$ in the domain of $T$

(ii) $T(\alpha u) = \alpha T(u)$ for all $\alpha \in \mathbb{R}$, all $u$ in the domain of $T$

The mapping of the second example given above is linear - but not for the first one.

If a mapping is linear then $T(0) = 0$. (Why?)

**Observation:** A mapping is linear if and only if

$$T(\alpha u + \beta v) = \alpha T(u) + \beta T(v)$$

for all scalars $\alpha, \beta$ and all $u, v$ in the domain of $T$.

Prove this
Given an $m \times n$ matrix $A$, consider the special mapping:

$$T : \mathbb{R}^n \longrightarrow \mathbb{R}^m$$

$$x \longrightarrow y = Ax$$

- Domain == ??; Image space == ??

From what we saw earlier ['Properties of the matrix-vector product'] such mappings are linear.

As it turns out:

If $T$ is linear, there exists a matrix $A$ such that $T(x) = Ax$ for all $x$ in $\mathbb{R}^n$.

In plain English: ‘A linear mapping can be represented by a matvec’

$A$ is the representation of $T$. 

7-5
Let $A$ be a square matrix. Is the mapping $x \rightarrow x + Ax$ linear? If so find the matrix associated with it.

Same questions for the mapping $x \rightarrow Ax + \alpha x$ - where $\alpha$ is a scalar.

Express the following mapping from $\mathbb{R}^3$ to $\mathbb{R}^2$ in matrix/vector form:

$$
\begin{align*}
y_1 &= 2x_1 - x_2 + 1 \\
y_2 &= x_2 - x_3 - 2
\end{align*}
$$

Is this a linear mapping?

Read Section 1.9 and explore the notions of onto mappings (‘surjective’) and one-to-one mappings (‘injective’) in the text. You must at least know the definitions.

A mapping is onto if and only if ....

A mapping is one-to-one if and only if ....
MATRIX OPERATIONS [2.1]
If \( \mathbf{A} \) is an \( m \times n \) matrix (\( m \) rows and \( n \) columns) – then the scalar entry in the \( i \)th row and \( j \)th column of \( \mathbf{A} \) is denoted by \( a_{ij} \) and is called the \((i, j)\)-entry of \( \mathbf{A} \).
The number $a_{ij}$ is the $i$th entry (from the top) of the $j$th column.

Each column of $A$ is a list of $m$ real numbers, which identifies a vector in $\mathbb{R}^m$ called a column vector.

The columns are denoted by $a_1, \ldots, a_n$, and the matrix $A$ is written as $A = [a_1, a_2, \ldots, a_n]$. 
The diagonal entries in an $m \times n$ matrix $A$ are $a_{11}, a_{22}, a_{33}, \ldots$, and they form the main diagonal of $A$.

A diagonal matrix is a matrix whose nondiagonal entries are zero.

An important example is the $n \times n$ identity matrix, $I_n$ (each diagonal entry equals one) - Example:

$$I_3 = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}$$

Another important matrix is the zero matrix (all entries are 0). It is denoted by $O$. 

Equality of two matrices: Two matrices $A$ and $B$ are equal if they have the same size (they are both $m \times n$) and if their entries are all the same.

\[ a_{ij} = b_{ij} \quad \text{for all } i = 1, \cdots, m, \quad j = 1, \cdots, n \]

Sum of two matrices: If $A$ and $B$ are $m \times n$ matrices, then their sum $A + B$ is the $m \times n$ matrix whose entries are the sums of the corresponding entries in $A$ and $B$.

If we call $C$ this sum we can write:

\[ c_{ij} = a_{ij} + b_{ij} \quad \text{for all } i = 1, \cdots, m, \quad j = 1, \cdots, n \]

\[
\begin{bmatrix}
4 & 0 & 5 \\
1 & 3 & 2
\end{bmatrix}
+ 
\begin{bmatrix}
3 & 1 & -3 \\
0 & 2 & -2
\end{bmatrix}
= ??; \\
\begin{bmatrix}
4 & 0 & 5 \\
1 & 3 & 2
\end{bmatrix}
+ 
\begin{bmatrix}
1 & -3 \\
2 & -2
\end{bmatrix}
= ??
\]
**Scalar multiple of a matrix** If $r$ is a scalar and $A$ is a matrix, then the scalar multiple $rA$ is the matrix whose entries are $r$ times the corresponding entries in $A$.

$$(\alpha A)_{ij} = \alpha a_{ij} \quad \text{for all } i = 1, \cdots, m, \quad j = 1, \cdots, n$$

**Theorem** Let $A$, $B$, and $C$ be matrices of the same size, and let $\alpha$ and $\beta$ be scalars. Then

- $A + B = B + A$
- $(A + B) + C = A + (B + C)$
- $A + 0 = A$
- $\alpha(A + B) = \alpha A + \alpha B$
- $(\alpha + \beta)A = \alpha A + \beta A$
- $\alpha(\beta A) = (\alpha \beta)A$

Prove all of the above equalities
When a matrix $B$ multiplies a vector $x$, it transforms $x$ into the vector $Bx$.

If this vector is then multiplied in turn by a matrix $A$, the resulting vector is $A(Bx)$.

Thus $A(Bx)$ is produced from $x$ by a composition of mappings—the linear transformations induced by $B$ and $A$.

Note: $x \rightarrow yA(Bx)$ is a linear mapping (prove this).
Goal: to represent this composite mapping as a multiplication by a single matrix, call it \( C \) for now, so that

\[
A(Bx) = Cx
\]

- Assume \( A \) is \( m \times n \), \( B \) is \( n \times p \), and \( x \) is in \( \mathbb{R}^p \)
- Denote the columns of \( B \) by \( b_1, \cdots, b_p \) and the entries in \( x \) by \( x_1, \cdots, x_p \). Then:

\[
Bx = x_1 b_1 + \cdots + x_p b_p
\]
By the linearity of multiplication by $A$:

\[
A(Bx) = A(x_1b_1) + \cdots + A(x_pb_p) \\
= x_1Ab_1 + \cdots + x_pAb_p
\]

The vector $A(Bx)$ is a linear combination of $Ab_1, \cdots, Ab_p$, using the entries in $x$ as weights.

In matrix notation, this linear combination is written as

\[
A(Bx) = [Ab_1, Ab_2, \cdots, Ab_p].x
\]

Thus, multiplication by $[Ab_1, Ab_2, \cdots, Ab_p]$ transforms $x$ into $A(Bx)$.

Therefore the desired matrix $C$ is the matrix

\[
C = [Ab_1, Ab_2, \cdots, Ab_p]
\]

Denoted by $AB$
**Definition:** If $A$ is an $m \times n$ matrix, and if $B$ is an $n \times p$ matrix with columns $b_1, \cdots, b_p$, then the product $AB$ is the matrix whose $p$ columns are $Ab_1, \cdots, Ab_p$. That is:

$$AB = A[b_1, b_2, \cdots, b_p] = [Ab_1, Ab_2, \cdots, Ab_p]$$

Important to remember that:

*Multiplication of matrices corresponds to composition of linear transformations.*

Operation count: How many operations are required to perform product $AB$?
Compute $AB$ when

$$A = \begin{bmatrix} 2 & -1 \\ 1 & 3 \end{bmatrix} \quad B = \begin{bmatrix} 0 & 2 & -1 \\ 1 & 3 & -2 \end{bmatrix}$$

Compute $AB$ when

$$A = \begin{bmatrix} 2 & -1 & 2 & 0 \\ 1 & -2 & 1 & 0 \\ 3 & -2 & 0 & 0 \end{bmatrix} \quad B = \begin{bmatrix} 1 & -1 & -2 \\ 0 & -2 & 2 \\ 2 & 1 & -2 \\ -1 & 3 & 2 \end{bmatrix}$$

Can you compute $AB$ when

$$A = \begin{bmatrix} 2 & -1 \\ 1 & 3 \end{bmatrix} \quad B = \begin{bmatrix} 0 & 2 \\ 1 & 3 \\ -1 & 4 \end{bmatrix}?$$
Row-wise matrix product

- Recall what we did with matrix-vector product to compute a single entry of the vector $Ax$.

- Can we do the same thing here? i.e., How can we compute the entry $c_{ij}$ of the product $AB$ without computing entire columns?

- Do this to compute entry $(2, 2)$ in the first example above.

- Operation counts: Is more or less expensive to perform the matrix-vector product row-wise instead of column-wise?
Properties of matrix multiplication

**Theorem** Let $A$ be an $m \times n$ matrix, and let $B$ and $C$ have sizes for which the indicated sums and products are defined.

- $A(BC) = (AB)C$ (associative law of multiplication)
- $A(B + C) = AB + AC$ (left distributive law)
- $(B + C)A = BA + CA$ (right distributive law)
- $\alpha(AB) = (\alpha A)B = A(\alpha B)$ for any scalar $\alpha$
- $I_mA = AI_n = A$ (product with identity)

If $AB = AC$ then $B = C$ (’simplification’) : True-False?

If $AB = 0$ then either $A = 0$ or $B = 0$ : True or False?

$AB = BA$ : True or false??
Square matrices. Matrix powers

- Important particular case when \( n = m \) - so matrix is \( n \times n \)
- In this case if \( x \) is in \( \mathbb{R}^n \) then \( y = Ax \) is also in \( \mathbb{R}^n \)
- \( AA \) is also a square \( n \times n \) matrix and will be denoted by \( A^2 \)
- More generally, the matrix \( A^k \) is the matrix which is the product of \( k \) copies of \( A \):
  \[
  A^1 = A; \quad A^2 = AA; \quad \ldots \quad A^k = A \cdots A
  \]
  \( k \) times
- For consistency define \( A^0 \) to be the identity: \( A^0 = I_n \),

\[ A^l \times A^k = A^{l+k} \] – Also true when \( k \) or \( l \) is zero.
**Transpose of a matrix**

Given an $m \times n$ matrix $A$, the transpose of $A$ is the $n \times m$ matrix, denoted by $A^T$, whose columns are formed from the corresponding rows of $A$.

**Theorem**: Let $A$ and $B$ denote matrices whose sizes are appropriate for the following sums and products.

- $(A^T)^T = A$
- $(A + B)^T = A^T + B^T$
- $(\alpha A)^T = \alpha A^T$ for any scalar $\alpha$
- $(AB)^T = B^T A^T$
Matrix operations: Matrix-vector product (review)

Product of the matrix $A$ by the vector $x$:

\[
\begin{bmatrix}
\beta_1 \\
\vdots \\
\beta_j \\
\vdots \\
\beta_n
\end{bmatrix}
= \begin{bmatrix}
a_{11} & \cdots & a_{1j} & \cdots & a_{1n} \\
\vdots & & \vdots & & \vdots \\
a_{i1} & \cdots & a_{ij} & \cdots & a_{in} \\
\vdots & & \vdots & & \vdots \\
a_{m1} & \cdots & a_{mj} & \cdots & a_{mn}
\end{bmatrix}
\begin{bmatrix}
\alpha_1 \\
\vdots \\
\alpha_j \\
\vdots \\
\alpha_n
\end{bmatrix}
\]

\[
= \alpha_1 a_1 + \alpha_2 a_2 + \cdots + \alpha_n a_n
\]

- $x, y$ are vectors; $y$ is the result of $A \times x$.
- $a_1, a_2, \ldots, a_n$ are the columns of $A$. 
• \( \alpha_1, \alpha_2, \ldots, \alpha_n \) are the components of \( x \) [scalars]

• \( \alpha_1 a_1 \) is the first column of \( A \) multiplied by the scalar \( \alpha_1 \) which is the first component of \( x \).

• \( \alpha_1 a_1 + \alpha_2 a_2 + \cdots + \alpha_n a_n \) is a linear combination of \( a_1, a_2, \ldots, a_n \) with weights \( \alpha_1, \alpha_2, \ldots, \alpha_n \).

This is the ‘column-wise’ form of the ‘matvec’

**Example:**

\[
A = \begin{bmatrix} 1 & 2 & -1 \\ 0 & -1 & 3 \end{bmatrix} \quad x = \begin{bmatrix} -2 \\ 1 \\ -3 \end{bmatrix} \quad y = ?
\]

**Result:**

\[
y = -2 \times \begin{bmatrix} 1 \\ 0 \end{bmatrix} + 1 \times \begin{bmatrix} 2 \\ -1 \end{bmatrix} - 3 \times \begin{bmatrix} -1 \\ 3 \end{bmatrix} = \begin{bmatrix} 3 \\ -10 \end{bmatrix}
\]
Can get $i$-th component of the result $y$ without the others:

$$\beta_i = \alpha_1 a_{i1} + \alpha_2 a_{i2} + \cdots + \alpha_n a_{in}$$

**Example:** In the above example extract $\beta_2$

$$\beta_2 = (-2) \times 0 + (1) \times (-1) + (-3) \times (3) = -10$$

Can compute $\beta_1, \beta_2, \cdots, \beta_m$ in this way.

This is the ‘row-wise’ form of the ‘matvec’
Matrix operations: Matrix-Matrix product

When $A$ is $m \times n$, $B$ is $n \times p$, the product $AB$ of the matrices $A$ and $B$ is the $m \times p$ matrix defined as

$$AB = [Ab_1, Ab_2, \cdots, Ab_p]$$

Each $Ab_j$ is a matrix-vector product: the product of $A$ by the $j$-th column of $B$. Matrix $AB$ has dimension $m \times p$

Can use what we know on matvecs to perform the product

1. Column form – In words: “The $j$-th column of $AB$ is a linear combination of the columns of $A$, with weights $b_{1j}, b_{2j}, \cdots, b_{nj}$” (entries of $j$-th col. of $B$)
**Example:**

\[
A = \begin{bmatrix}
1 & 2 & -1 \\
0 & -1 & 3
\end{bmatrix} \quad B = \begin{bmatrix}
-2 & 1 \\
1 & -2 \\
-3 & 2
\end{bmatrix} \quad AB = ?
\]

\[
B = \begin{bmatrix}
1 & 2 & -1 \\
0 & -1 & 3
\end{bmatrix} \begin{bmatrix}
-2 \\
1 \\
-3
\end{bmatrix}, \quad \begin{bmatrix}
1 & 2 & -1 \\
0 & -1 & 3
\end{bmatrix} \begin{bmatrix}
1 \\
-2 \\
2
\end{bmatrix}
\]

\[
= \begin{bmatrix}
3 & -6 \\
-10 & 8
\end{bmatrix}
\]

First column has been computed before: it is equal to:
\[
(-2)*(\text{col. 1 of } A) + (1)*(\text{col. 2 of } A) + (-3)*(\text{col. 3 of } A)
\]

Second column is equal to:
\[
(1)*(\text{col. 1 of } A) + (-2)*(\text{col. 2 of } A) + (2)*(\text{col. 3 of } A)
\]
2. If we call $C$ the matrix $C = AB$ what is $c_{ij}$? From above:

$$c_{ij} = a_{i1}b_{1j} + a_{i2}b_{2j} + \ldots + a_{ik}b_{kj} + \ldots + a_{in}b_{nj}$$

- Fix $j$ and run $i \rightarrow$ column-wise form just seen

3. Fix $i$ and run $j \rightarrow$ row-wise form

**Example:** Get second row of $AB$ in previous example.

$$c_{2j} = a_{21}b_{1j} + a_{22}b_{2j} + a_{23}b_{3j}, \quad j = 1, 2$$

- Can be read as: $$c_{2:} = a_{21}b_{1:} + a_{22}b_{2:} + a_{23}b_{3:}$$, or in words:

row2 of $C = a_{21}$ (row1 of B) + $a_{22}$ (row2 of B) + $a_{23}$ (row3 of B)

= $0$ (row1 of B) + (-1) (row2 of B) + (3) (row3 of B)

= $[-10 \quad 8]$
