Address Spaces
- Linear address space: Ordered set of contiguous non-negative integer addresses:
  \[ \{0, 1, 2, 3 \ldots \} \]
- Virtual address space: Set of \( N = 2^n \) virtual addresses
  \[ \{0, 1, 2, 3, \ldots, N-1\} \]
- Physical address space: Set of \( M = 2^m \) physical addresses
  \[ \{0, 1, 2, 3, \ldots, M-1\} \]

Why Virtual Memory (VM)?
- Uses main memory efficiently
  - Use DRAM as a cache for parts of a virtual address space
- Simplifies memory management
  - Each process gets the same uniform linear address space
- Isolates address spaces
  - One process can’t interfere with another’s memory
  - User program cannot access privileged kernel information and code

A System Using Physical Addressing
- Used in “simple” systems like embedded microcontrollers in devices like cars, elevators, and digital picture frames

A System Using Virtual Addressing
- Used in all modern servers, laptops, and smart phones
- One of the great ideas in computer science

- VM as a tool for memory management
- VM as a tool for memory protection
- Address translation

VM as a Tool for Caching
- Conceptually, virtual memory is an array of N contiguous bytes stored on disk.
- The contents of the array on disk are cached in physical memory (DRAM cache)
  - These cache blocks are called pages (size is \( P = 2^p \) bytes)

DRAM Cache Organization
- DRAM cache organization driven by the enormous miss penalty
  - DRAM is about 10x slower than SRAM
  - Disk is about 10,000x slower than DRAM

  Consequences
  - Large page (block) size: typically 4 KB, sometimes 4 MB
  - Fully associative
    - Any VP can be placed in any PP
  - Requires a "large" mapping function – different from cache memories
  - Too complicated and open-ended to be implemented in hardware
  - Write-back rather than write-through

Enabling Data Structure: Page Table
- A page table is an array of page table entries (PTEs) that maps virtual pages to physical pages.
- Per-process kernel data structure in DRAM

Page Hit
- Page hit: reference to VM word that is in physical memory (DRAM cache hit)

Page Fault
- Page fault: reference to VM word that is not in physical memory (DRAM cache miss)
Handling Page Fault

- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)
- Offending instruction is restarted: page hit!

Key point: Waiting until the miss to copy the page to DRAM is known as demand paging.

Allocating Pages

- Allocating a new page (VP 5) of virtual memory.

Locality to the Rescue Again!

- Virtual memory seems terribly inefficient, but it works because of locality.
- At any point in time, programs tend to access a set of active virtual pages called the working set
  - Programs with better temporal locality will have smaller working sets
- If (working set size < main memory size)
  - Good performance for one process after compulsory misses
- If (SUM(working set sizes) > main memory size)
  - Thrashing: Performance meltdown where pages are swapped (copied) in and out continuously

VM as a Tool for Memory Management

- Key idea: each process has its own virtual address space
  - It can view memory as a simple linear array
  - Mapping function scatters addresses through physical memory
    - Well-chosen mappings can improve locality
- Virtual Address Space for Process 1:
  - VP 1
  - VP 2
  - PP 6
  - N-1

- Shared code and data among processes
  - Map virtual pages to the same physical page (here: PP 6)

Simplifying Linking and Loading

- Linking
  - Each program has similar virtual address space
  - Code, data, and heap always start at the same addresses.
- Loading
  - execve allocates virtual pages for .text and .data sections & creates PTEs marked as invalid
  - The .text and .data sections are copied, page by page, on demand by the virtual memory system

VM as a Tool for Memory Protection

- Extend PTEs with permission bits
- MMU checks these bits on each access

Memory invisible to user code

- Kernel virtual memory
- User stack (created at runtime)
- Memory-mapped region for shared libraries

User stack

- Stack
- Stack

- Linked list

- Run-time heap
  - Created by malloc

- Read/write segment (.data, .bss)
- Read-only segment (.text, .rodata)

VM Address Translation

- Virtual Address Space
  - \( V = \{0, 1, ..., N-1\} \)
- Physical Address Space
  - \( P = \{0, 1, ..., M-1\} \)
- Address Translation
  - MAP: \( V \rightarrow P \cup \{\emptyset\} \)
  - For virtual address \( a \):
    - \( MAP(a) = a' \) if data at virtual address \( a \) is at physical address \( a' \) in \( P \)
    - \( MAP(a) = \emptyset \) if data at virtual address \( a \) is not in physical memory
      - Either invalid or stored on disk

Summary of Address Translation Symbols

- Basic Parameters
  - \( N = 2^n \): Number of addresses in virtual address space
  - \( M = 2^m \): Number of addresses in physical address space
  - \( P = 2^p \): Page size (bytes)
- Components of the virtual address (VA)
  - TLBI: TLB index
  - TLBT: TLB tag
  - VPO: Virtual page offset
  - VPN: Virtual page number
- Components of the physical address (PA)
  - PPO: Physical page offset (same as VPO)
  - PPN: Physical page number

Address Translation With a Page Table

Address Translation: Page Hit

1. Processor sends virtual address to MMU
2-3. MMU fetches PTE from page table in memory
4. MMU sends physical address to cache/memory
5. Cache/memory sends data word to processor

Address Translation: Page Fault

1. Processor sends virtual address to MMU
2-3. MMU fetches PTE from page table in memory
4. Valid bit is zero, so MMU triggers page fault exception
5. Handler identifies victim (and, if dirty, pages it out to disk)
6. Handler pages in new page and updates PTE in memory
7. Handler returns to original process, restarting faulting instruction
Integrating VM and Cache

Page table entries (PTEs) are cached in L1 like any other memory word
- PTEs may be evicted by other data references
- PTE hit still requires a small L1 delay
**Solution:** Translation Lookaside Buffer (TLB)
- Small set-associative hardware cache in MMU
- Maps virtual page numbers to physical page numbers
- Contains complete page table entries for small number of pages

Accessing the TLB

- MMU uses the VPN portion of the virtual address to access the TLB:
  - TLBI matches tag of line within set
  - T = 2^s sets
  - Set 0
    - PTE
  - Set 1
    - PTE
  - Set T-1
    - PTE

TLB Hit

- A TLB hit eliminates a memory access

TLB Miss

- A TLB miss incurs an additional memory access (the PTE)
- Fortunately, TLB misses are rare. Why?

Multi-Level Page Tables

- **Suppose:**
  - 4KB \(2^{12}\) page size, 48-bit address space, 8-byte PTE
- **Problem:**
  - Would need a 512 GB page table!
  - \(2^{36} \times 2^{12} \times 2^2 = 2^{39}\) bytes
- **Common solution:** Multi-level page table
- **Example:** 2-level page table
  - Level 1 table: each PTE points to a page table (always memory resident)
  - Level 2 table: each PTE points to a page (paged in and out like any other data)
A Two-Level Page Table Hierarchy

- Level 1 page table
- Level 2 page tables
- Virtual memory

32 bit addresses, 4K pages, 4-byte PTEs

Summary

- **Programmer’s view of virtual memory**
  - Each process has its own private linear address space
  - Cannot be corrupted by other processes

- **System view of virtual memory**
  - Uses memory efficiently by caching virtual memory pages
  - Efficient only because of locality
  - Simplifies memory management and programming
  - Simplifies protection by providing a convenient interpositioning point to check permissions
