## Eigenvalue Problems. Introduction

Let A an  $n \times n$  real nonsymmetric matrix. The eigenvalue problem:

 $egin{aligned} Ax &= \lambda x \ x &\in \mathbb{C}^n: ext{ eigenvalue} \ x &\in \mathbb{C}^n: ext{ eigenvector} \end{aligned}$ 

### Types of Problems:

- ullet Compute a few  $\lambda_i$  's with smallest or largest real parts;
- Compute all  $\lambda_i$ 's in a certain region of  $\mathbb{C}$ ;
- Compute a few of the dominant eigenvalues;
- Compute all  $\lambda_i$ 's.

# Basic definitions and properties

A complex scalar  $\lambda$  is called an eigenvalue of a square matrix A if there exists a nonzero vector u in  $\mathbb{C}^n$  such that  $Au = \lambda u$ . The vector u is called an eigenvector of A associated with  $\lambda$ . The set of all eigenvalues of A is the 'spectrum' of A. Notation:  $\Lambda(A)$ .

12-2

>  $\lambda$  is an eigenvalue iff the columns of  $A - \lambda I$  are linearly dependent.

 $\blacktriangleright$  ... equivalent to saying that its rows are linearly dependent. So: there is a nonzero vector w such that

$$w^H(A-\lambda I)=0$$

12-4

- $\blacktriangleright w$  is a left eigenvector of A (u= right eigenvector)
- $\blacktriangleright \ \lambda$  is an eigenvalue iff  $\overline{\det(A-\lambda I)=0}$

12-3

# Basic definitions and properties (cont.)

An eigenvalue is a root of the Characteristic polynomial:

$$p_A(\lambda) = \det(A - \lambda I)$$

So there are n eigenvalues (counted with their multiplicities).

> The multiplicity of these eigenvalues as roots of  $p_A$  are called algebraic multiplicities.

> The geometric multiplicity of an eigenvalue  $\lambda_i$  is the number of linearly independent eigenvectors associated with  $\lambda_i$ .

Geometric multiplicity is < algebraic multiplicity.</p>

An eigenvalue is simple if its (algebraic) multiplicity is one.

► It is semi-simple if its geometric and algebraic multiplicities are equal.

**∠**<sub>1</sub> Consider

$$A = egin{pmatrix} 1 & 2 & -4 \ 0 & 1 & 2 \ 0 & 0 & 2 \ \end{pmatrix}$$

Eigenvalues of *A*? their algebraic multiplicities? their geometric multiplicities? Is one a semi-simple eigenvalue?

**Z**<sub>12</sub> Same questions if  $a_{33}$  is replaced by one.

Z<sub>13</sub> Same questions if, in addition,  $a_{12}$  is replaced by zero.

12-5 GvL 7.1-7.4,7.5.2 - Eigen	12-6 GvL 7.1-7.4,7.5.2 - Eigen
12-5	12-6
Two matrices $A$ and $B$ are similar if there exists a nonsingular matrix $X$ such that	Transformations that preserve eigenvectors
$A = XBX^{-1}$	Shift $B = A - \sigma I$ : $Av = \lambda v \iff Bv = (\lambda - \sigma)v$

 $\mathbf{v} = \mathbf{v} (\mathbf{v} = 1 \mathbf{v})$ 

►  $Av = \lambda v \iff B(X^{-1}v) = \lambda(X^{-1}v)$ eigenvalues remain the same, eigenvectors transformed.

 $\blacktriangleright$  Issue: find X so that B has a simple structure

*Definition:* **A** is diagonalizable if it is similar to a diagonal matrix

 $\blacktriangleright$  THEOREM: A matrix is diagonalizable iff it has n linearly independent eigenvectors

12-7

> ... iff all its eigenvalues are semi-simple

 $\succ$  ... iff its eigenvectors form a basis of  $\mathbb{R}^n$ 

GvL 7.1-7.4,7.5.2 - Eigen

- Shift  $B = A \sigma I$ :  $Av = \lambda v \iff Bv = (\lambda \sigma)v$ eigenvalues move, eigenvectors remain the same.
- Polynomial  $B = p(A) = \alpha_0 I + \dots + \alpha_n A^n$ :  $Av = \lambda v \iff$  $Bv = p(\lambda)v$ eigenvalues transformed, eigenvectors remain the same.
- Invert  $B = A^{-1}$ :  $Av = \lambda v \iff Bv = \lambda^{-1}v$ eigenvalues inverted, eigenvectors remain the same.
- Shift &  $B = (A \sigma I)^{-1}$ :  $Av = \lambda v \iff Bv =$ Invert  $(\lambda - \sigma)^{-1}v$

12-8

eigenvalues transformed, eigenvectors remain the same. spacing between eigenvalues can be radically changed.

12-8

> THEOREM (Schur form): Any matrix is unitarily similar to a triangular matrix, i.e., for any A there exists a unitary matrix Q and an upper triangular matrix R such that

 $A = QRQ^H$ 

Any Hermitian matrix is unitarily similar to a real diagonal matrix, (i.e. its Schur form is real diagonal).

> It is easy to read off the eigenvalues (including all the multiplicities) from the triangular matrix R

Eigenvectors can be obtained by back-solving

Schur Form – Proof

**Solution** Show that there is at least one eigenvalue and eigenvector of **A**:  $Ax = \lambda x$ , with  $||x||_2 = 1$ 

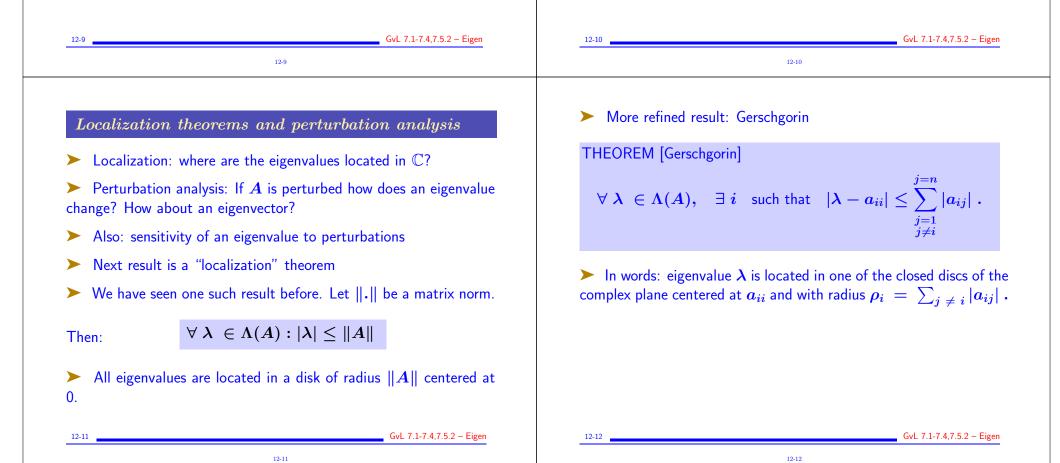

**Model** There is a unitary transformation P such that  $Px = e_1$ . How do you define P?

**Z**<sub>16</sub> Show that  $PAP^{H} = \left( rac{\lambda | **}{0 | A_2} 
ight).$ 

**Z**<sub>17</sub> Apply process recursively to  $A_2$ .

🌆 What happens if  $oldsymbol{A}$  is Hermitian?

Another proof altogether: use Jordan form of  $\boldsymbol{A}$  and QR factorization

**Proof:** By contradiction. If contrary is true then there is one eigenvalue  $\lambda$  that does not belong to any of the disks, i.e., such that  $|\lambda - a_{ii}| > \rho_i$  for all *i*. Write matrix  $A - \lambda I$  as:

$$A - \lambda I = D - \lambda I - [D - A] \equiv (D - \lambda I) - F$$

where D is the diagonal of A and -F = -(D - A) is the matrix of off-diagonal entries. Now write

 $A - \lambda I = (D - \lambda I)(I - (D - \lambda I)^{-1}F).$ 

From assumptions we have  $\|(D - \lambda I)^{-1}F\|_{\infty} < 1$ . (Show this). The Lemma in P. 5-3 of notes would then show that  $A - \lambda I$  is nonsingular – a contradiction  $\Box$ 

### Gerschgorin's theorem - example

 $\swarrow_{10}$  Find a region of the complex plane where the eigenvalues of the following matrix are located:

$$A = egin{pmatrix} 1 & -1 & 0 & 0 \ 0 & 2 & 0 & 1 \ -1 & -2 & -3 & 1 \ rac{1}{2} & rac{1}{2} & 0 & -4 \end{pmatrix}$$

▶ Refinement: if disks are all disjoint then each of them contains one eigenvalue

> Refinement: can combine row and column version of the theorem (column version: apply theorem to  $A^H$ ).

12-13 GvL 7.1-7.4,7.5.2 - Eiger GvL 7.1-7.4,7.5.2 – Eigen 12-13 12-14 Bauer-Fike theorem Conditioning of Eigenvalues THEOREM [Bauer-Fike] Let  $\hat{\lambda}, \tilde{u}$  be an approximate eigenpair with > Assume that  $\lambda$  is a simple eigenvalue with right and left eigen- $\|\tilde{u}\|_2 = 1$ , and let  $r = A\tilde{u} - \tilde{\lambda}\tilde{u}$  ('residual vector'). Assume vectors u and  $w^H$  respectively. Consider the matrices: A is diagonalizable:  $A = XDX^{-1}$ , with D diagonal. Then Eigenvalue  $\lambda(t)$ . A(t) = A + tE $\exists \ \lambda \in \ \Lambda(A)$  such that  $|\lambda - \tilde{\lambda}| \leq \operatorname{cond}_2(X) \|r\|_2$ . Eigenvector u(t). Conditioning of  $\lambda$  of A relative to E is  $\left|\frac{d\lambda(t)}{dt}\right|_{t=0}$ . Very restrictive result - also not too sharp in general.  $\succ$  $A(t)u(t) = \lambda(t)u(t)$ Write  $\succ$  $\blacktriangleright$  Alternative formulation. If E is a perturbation to A then for any eigenvalue  $\lambda$  of A + E there is an eigenvalue  $\lambda$  of A such that: Then multiply both sides to the left by  $w^H$  $w^{H}(A+tE)u(t)=\lambda(t)w^{H}u(t)$  ightarrow $|\lambda - ilde{\lambda}| \leq {
m cond}_2(X) \|E\|_2$  .  $\lambda(t)w^{H}u(t) = w^{H}Au(t) + tw^{H}Eu(t)$  $= \lambda w^H u(t) + t w^H E u(t).$ 12-15 GvL 7.1-7.4,7.5.2 - Eigen GvL 7.1-7.4,7.5.2 - Eigen 12-15 12-16

$$ightarrow rac{\lambda(t)-\lambda}{t}w^{H}u(t) = w^{H}Eu(t)$$
  
Take the limit at  $t=0$ ,  $\lambda'(0) = rac{w^{H}Eu}{w^{H}u}$ 

▶ Note: the left and right eigenvectors associated with a simple eigenvalue cannot be orthogonal to each other.

Actual conditioning of an eigenvalue, given a perturbation "in the direction of E" is  $|\lambda'(0)|$ .

In practice only estimate of ||E|| is available, so

$ \lambda'(0)  <$	$\ \boldsymbol{E} \boldsymbol{u}\ _2 \ \boldsymbol{w}\ _2$	$\leq \ E\ _2 rac{\ u\ _2 \ w\ _2}{ (u,w) }$
$ \lambda(0)  \leq$	(u,w)	$\leq \ L\ _2$ $ (u,w) $

12-17

**Definition**. The condition number of a simple eigenvalue  $\lambda$  of an arbitrary matrix A is defined by

$$\operatorname{\mathsf{cond}}(\lambda) = rac{1}{\cos heta(u,w)}$$

in which u and  $w^H$  are the right and left eigenvectors, respectively, associated with  $\lambda$ .

**Example:** Consider the matrix

$$A=egin{pmatrix} -149 & -50 & -154\ 537 & 180 & 546\ -27 & -9 & -25 \end{pmatrix}$$

12-18

GvL 7.1-7.4,7.5.2 - Eigen

Perturbations with Multiple Eigenvalues - Example

Consider
$$A = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}$$

12-18

- > Worst case perturbation is in 3,1 position: set  $A_{31} = \epsilon$ .
- ► Eigenvalues of perturbed **A** are the roots of  $p(\mu) = (\mu 1)^3 4 \cdot \epsilon$ .
- > Roots:  $\mu_k = 1 + (4\epsilon)^{1/3} e^{\frac{2ki\pi}{3}}, \quad k = 1, 2, 3$
- > Hence eigenvalues of perturbed A are  $1 + O(\sqrt[3]{\epsilon})$ .
- ▶ If index of eigenvalue (dimension of largest Jordan block) is k, then an  $O(\epsilon)$  perturbation to A leads to  $O(\sqrt[k]{\epsilon})$  change in eigenvalue. Simple eigenvalue case corresponds to k = 1.

12-20

>  $\Lambda(A) = \{1, 2, 3\}$ . Right and left eigenvectors associated with  $\lambda_1 = 1$ :

$$u = egin{pmatrix} 0.3162 \ -0.9487 \ 0.0 \end{pmatrix}$$
 and  $w = egin{pmatrix} 0.6810 \ 0.2253 \ 0.6967 \end{bmatrix}$ 

So:  $cond(\lambda_1) \approx 603.64$ 

> Perturbing  $a_{11}$  to -149.01 yields the spectrum:

 $\{0.2287, 3.2878, 2.4735\}.$ 

For Hermitian (also normal matrices) every simple eigenvalue is well-conditioned, since  $cond(\lambda) = 1$ .

## Basic algorithm: The power method

**>** Basic idea is to generate the sequence of vectors  $A^k v_0$  where  $v_0 \neq 0$  – then normalize.

▶ Most commonly used normalization: ensure that the largest component of the approximation is equal to one.

The Power Method1. Choose a nonzero initial vector  $v^{(0)}$ .2. For  $k = 1, 2, \ldots$ , until convergence, Do:3.  $\alpha_k = \operatorname{argmax}_{i=1,\ldots,n} |(Av^{(k-1)})_i|$ 4.  $v^{(k)} = \frac{1}{\alpha_k} Av^{(k-1)}$ 5. EndDo

 $\blacktriangleright$  Note that  $A^k u_i = \lambda_i^k u_i$ 

$$egin{aligned} v^{(k)} &= rac{1}{scaling} \, imes \, \sum_{i=1}^n \lambda_i^k \gamma_i u_i \ &= rac{1}{scaling} \, imes \, \left[ \lambda_1^k \gamma_1 u_1 + \sum_{i=2}^n \lambda_i^k \gamma_i^k u_i 
ight] \ &= rac{1}{scaling'} \, imes \, \left[ u_1 + \sum_{i=2}^n \left( rac{\lambda_i}{\lambda_1} 
ight)^k rac{\gamma_i}{\gamma_1} u_i 
ight] \end{aligned}$$

Second term inside bracket converges to zero. QED

Proof suggests that the convergence factor is given by

$$ho_D = rac{|m{\lambda}_2|}{|m{\lambda}_1|}$$

12-23

where  $\lambda_2$  is the second largest eigenvalue in modulus.

12-23

GvL 7.1-7.4,7.5.2 - Eigen

### Convergence of the power method

THEOREM Assume there is one eigenvalue  $\lambda_1$  of A, s.t.  $|\lambda_1| > |\lambda_j|$ , for  $j \neq i$ , and that  $\lambda_1$  is semi-simple. Then either the initial vector  $v^{(0)}$  has no component in Null $(A - \lambda_1 I)$  or  $v^{(k)}$  converges to an eigenvector associated with  $\lambda_1$  and  $\alpha_k \rightarrow \lambda_1$ .

Proof in the diagonalizable case.

 $\succ v^{(k)}$  is = vector  $A^k v^{(0)}$  normalized by a certain scalar  $\hat{\alpha}_k$  in such a way that its largest component is 1.

> Decompose initial vector  $v^{(0)}$  in the eigenbasis as:

$$v^{(0)} = \sum_{i=1}^n \gamma_i u_i$$

GvL 7.1-7.4,7.5.2 - Eigen

 $\succ$  Each  $u_i$  is an eigenvector associated with  $\lambda_i$ .

**Example:** Consider a 'Markov Chain' matrix of size n = 55. Dominant eigenvalues are  $\lambda = 1$  and  $\lambda = -1 >$  the power method applied directly to A fails. (Why?)

12-22

> We can consider instead the matrix I + A The eigenvalue  $\lambda = 1$  is then transformed into the (only) dominant eigenvalue  $\lambda = 2$

# The Shifted Power Method

In previous example shifted A into B = A + I before applying power method. We could also iterate with  $B(\sigma) = A + \sigma I$  for any positive  $\sigma$ 

Example:	With $\sigma = 0.1$ we get the following improvement.
----------	---

Iteration	Norm of diff.	Res. Norm	Eigenvalue
20			1.00524001
40			1.00016755
60	0.183D-04	0.509D-05	1.00000446
80	0.437D-06	0.118D-06	1.00000011
88	0.971D-07	0.261D-07	1.0000002

- > Question: What is the best shift-of-origin  $\sigma$  to use?
- Easy to answer the question when all eigenvalues are real.Assume all eigenvalues are real and labeled decreasingly:

$$\lambda_1 > \lambda_2 \geq \lambda_2 \geq \cdots \geq \lambda_n,$$

Then: If we shift A to  $A - \sigma I$ :

The shift  $\sigma$  that yields the best convergence factor is:

$$\sigma_{opt} = rac{\lambda_2 + \lambda_n}{2}$$

**Plot** a typical convergence factor  $\phi(\sigma)$  as a function of  $\sigma$ . Determine the minimum value and prove the above result.
