CSci 4271W Development of Secure Software Systems Day 5: Threat modeling, memory safety attacks

Stephen McCamant University of Minnesota, Computer Science & Engineering

Outline

Threat modeling, cont'd

Shellcode techniques

Examples in GDB

Exploiting other vulnerabilities

Attacks come with data flows

Principle: attacks propagate along data flows

- Therefore, enumerate flows to enumerate attacks
 - A more specific prompt, but does not eliminate the need for imagination
 - Other half is types of attacks, see next slide

STRIDE threat taxonomy

- Spoofing (vs authentication)
- 🖲 Tampering (vs integrity)
- Repudiation (vs. non-repudiation)
- Information disclosure (vs. confidentiality)
- Denial of service (vs. availability)
- Elevation of privilege (vs. authortization)

What to do about threats

- Mitigate: add a defense, which may not be complete
- Eliminate: such as by removing functionality
- Transfer functionality: let someone else handle it
- Transfer risk: convince another to bear the cost
- Accept risk: decide that the risk (probability · loss) is sufficiently low

Spoofing threat examples

- 🖲 Using someone else's account
- Making a program use the wrong file
- False address on network traffic

Tampering threat examples

- Modifying an important file
- Rearranging directory structure
- Changing contents of network packets

Repudiation threat examples

- Performing an important action without logging
- Destroying existing logs
- Add fake events to make real events hard to find or not credible

Info. disclosure threat examples

Eavesdropping on network traffic

- Reading sensitive files
- Learning sensitive information from meta-data

DoS threat examples

- Flood network link with bogus traffic
- Make a server use up available memory
- Make many well-formed but non-productive interactions

Elevation of privilege threat examples

- Cause data to be interpreted as code
- Change process to run as root/administrator
- Convince privileged process to run attacker's code

Outline

Threat modeling, cont'd

- Shellcode techniques
- Examples in GDB
- Exploiting other vulnerabilities

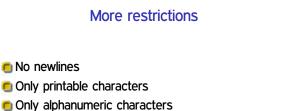

Basic definition

- Shellcode: attacker supplied instructions implementing malicious functionality
- Name comes from example of starting a shell
- Often requires attention to machine-language encoding

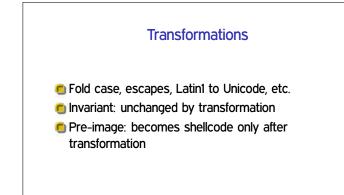

Classic execve /bin/sh

- 🛑 execve(fname, argv, envp) system call
- Specialized syscall calling conventions
- Omit unneeded arguments
- Doable in under 25 bytes for Linux/x86

Avoiding zero bytes Common requirement for shellcode in C string Analogy: broken 0 key on keyboard May occur in other parts of encoding as well Control of the string Control

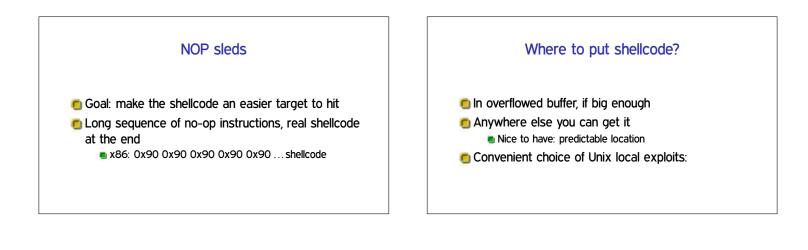

"English Shellcode" (CCS'09)

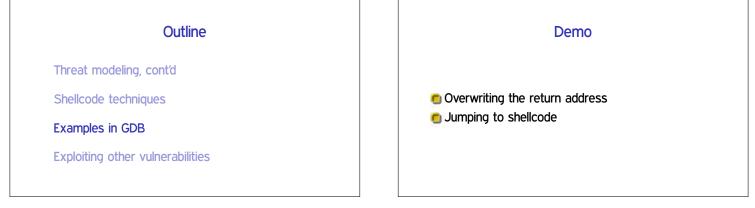

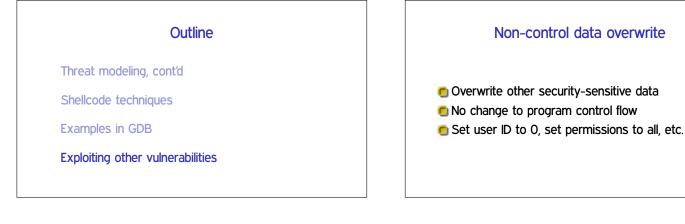

Multi-stage approach

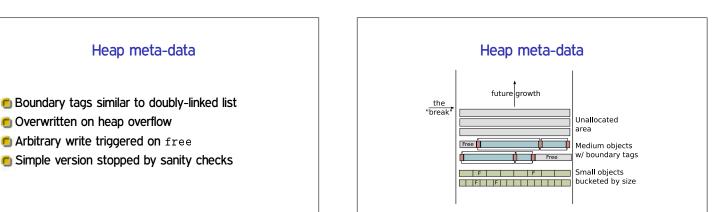

- Initially executable portion unpacks rest from another format
- Improves efficiency in restricted environments
- 🖲 But self-modifying code has pitfalls

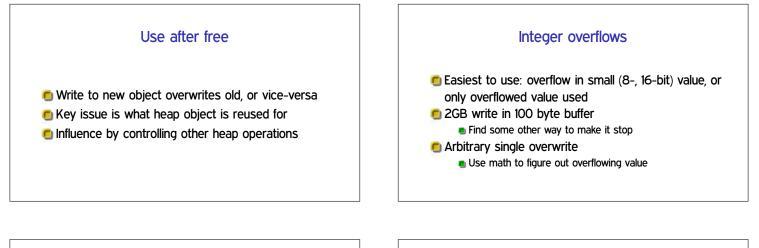

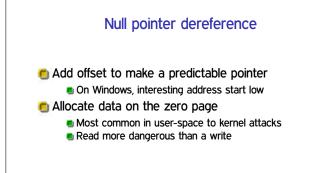

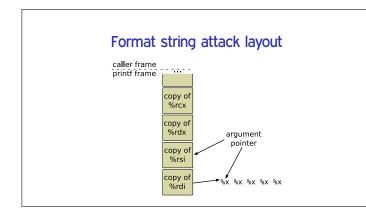

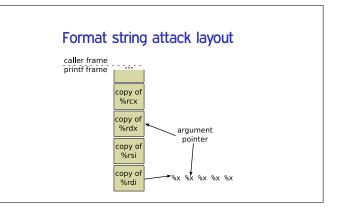

Overwritten on heap overflow

Attacker-controlled format: little interpreter Step one: add extra integer specifiers, dump stack Already useful for information disclosure

Format string attack: overwrite

- %n specifier: store number of chars written so far to pointer arg
- Advance format arg pointer to other attacker-controlled data
- Control number of chars written with padding
- On x86, can use unaligned stores to create pointer
