CSci 427IW Development of Secure Software Systems Day 19: Cryptography part 3, block ciphers and integrity Stephen McCamant

University of Minnesota, Computer Science & Engineering

Outline

Block ciphers and modes of operation, cont'd Announcements intermission Hash functions and MACs Building a secure channel

Public-key crypto basics

Substitution/permutation network

Parallel structure combining reversible elements:
 Substitution: invertible lookup table ("S-box")

Permutation: shuffle bits

Feistel cipher

- Split block in half, operate in turn: $(L_{i+1}, R_{i+1}) = (R_i, L_i \oplus F(R_i, K_i))$
- Key advantage: F need not be invertible
 Also saves space in hardware
- Luby-Rackoff: if F is pseudo-random, 4 or more rounds gives a strong PRP

DES

- Data Encryption Standard: AES predecessor 1977-2005
- 🖲 64-bit block, 56-bit key
- Implementable in 70s hardware, not terribly fast in software
- Triple DES variant still used in places

Some DES history

- Developed primarily at IBM, based on an earlier cipher named "Lucifer"
- Final spec helped and "helped" by the NSA Argued for smaller key size
 - S-boxes tweaked to avoid a then-secret attack
- Eventually victim to brute-force attack

DES brute force history

1977 est. \$20m cost custom hardware

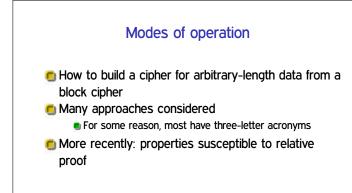

- 1993 est. \$1m cost custom hardware
- 1997 distributed software break
- 1998 \$250k built ASIC hardware

2006 \$10k FPGAs

2012 as-a-service against MS-CHAPv2

Double encryption?

- Combine two different block ciphers?
 Belt and suspenders
- 🖲 Anderson: don't do it
- FS&K: could do it, not a recommendation
- Maurer and Massey (J.Crypt'93): might only be as strong as first cipher

ECB

- Electronic CodeBook
- Split into blocks, apply cipher to each one individually
- Leaks equalities between plaintext blocks
- Almost never suitable for general use

CBC: getting an IV

C₀ is called the initialization vector (IV)
 Must be known for decryption
 IV should be random-looking
 To prevent first-block equalities from leaking (lesser version of ECB problem)

Common approaches

- Generate at random
- Encrypt a nonce

Public-key crypto basics

Stream modes: OFB, CTR

Output FeedBack: produce keystream by repeatedly encrypting the IV

Danger: collisions lead to repeated keystream

Counter: produce from encryptions of an incrementing value

> Recently becoming more popular: allows parallelization and random access

Next reading will be a chapter from Anderson about cryptography

Reading quiz on OWASP is ready, due next Tuesday

Various announcements

Active Project 0.5 discussion now on Piazza Including a common question about goto and code

injection

4/4

Hash functions and MACs

Building a secure channel

Public-key crypto basics

Ideal model

- Ideal crypto hash function: pseudorandom function
 Arbitrary input, fixed-size output
- Simplest kind of elf in box, theoretically very convenient
- But large gap with real systems: common practice is to target particular properties

Kinds of attacks

- **O** Pre-image, "inversion": given y, find x such that H(x) = y
- Second preimage, targeted collision: given x, H(x), find $x' \neq x$ such that H(x') = H(x)
- **(Free) collision:** find x_1 , x_2 such that $H(x_1) = H(x_2)$

Birthday paradox and attack

There are almost certainly two people in this class with the same birthday

o n people have $\binom{n}{2} = \Theta(n^2)$ pairs

- **5** So only about \sqrt{n} expected for collision
- "Birthday attack" finds collisions in any function

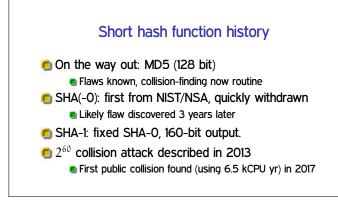

Security levels

For function with k-bit output:

- Preimage and second preimage should have complexity 2^k
- Collision has complexity 2^{k/2}
- Conservative: use hash function twice as big as block cipher key
 - Though if you're paranoid, cipher blocks can repeat too

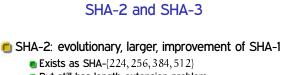

Non-cryptographic hash functions

- The ones you probably use for hash tables
- 🖲 CRCs, checksums
- Output too small, but also not resistant to attack
- E.g., CRC is linear and algebraically nice

Length extension problem

- MD5, SHA1, etc., computed left to right over blocks
- **Or Can sometimes compute** $H(a \parallel b)$ in terms of H(a)
 - means bit string concatenation
- Makes many PRF-style constructions insecure

- But still has length-extension problem
- 5 SHA-3: chosen recently in open competition like AES
 - Formerly known as Keccak, official standard Aug. 2015
 - New design, fixes length extension
 - Adoption has been gradual

MAC: basic idea

- Message authentication code: similar to hash function, but with a key
- Adversary without key cannot forge MACs
- Strong definition: adversary cannot forge anything, even given chosen-message MACs on other messages

CBC-MAC construction

Same process as CBC encryption, but:

- Start with IV of 0
- Return only the last ciphertext block
- Both these conditions needed for security
- For fixed-length messages (only), as secure as the block cipher

HMAC construction

■ H(K || M): insecure due to length extension
■ Still not recommended: H(M || K), H(K || M || K)
■ HMAC: H(K ⊕ a || H(K ⊕ b || M))
■ Standard a = 0x5 c*, b = 0x36*
■ Probably the most widely used MAC

Hash functions and MACs

Building a secure channel

Public-key crypto basics

Session keys

- Don't use your long term password, etc., directly as a key
- Instead, session key used for just one channel
- In modern practice, usually obtained with public-key crypto
- Separate keys for encryption and MACing

Order of operations

Encrypt and MAC ("in parallel")

Safe only under extra assumptions on the MAC

Encrypt then MAC

- Has cleanest formal safety proof
- MAC then Encrypt
 - Preferred by FS&K for some practical reasons
 - Can also be secure

Authenticated encryption modes

- Encrypting and MACing as separate steps is about twice as expensive as just encrypting
- "Authenticated encryption" modes do both at once
 Newer (circa 2000) innovation, many variants
- NIST-standardized and unpatented: Galois Counter Mode (GCM)

- Also don't want attacker to be able to replay or reorder messages
- Simple approach: prefix each message with counter
- Discard duplicate/out-of-order messages

Padding

- Adjust message size to match multiple of block size
- To be reversible, must sometimes make message longer
- E.g.: for 16-byte block, append either 1, or 2 2, or 3 3 3, up to 16 "16" bytes

Padding oracle attack

- Have to be careful that decoding of padding does not leak information
- E.g., spend same amount of time MACing and checking padding whether or not padding is right
- Remote timing attack against CBC TLS published 2013

Don't actually reinvent the wheel

- This is all implemented carefully in OpenSSL, SSH, etc.
- Good to understand it, but rarely sensible to reimplement it
- You'll probably miss at least one of decades' worth of attacks

Outline

Block ciphers and modes of operation, cont'd

Announcements intermission

Hash functions and MACs

Building a secure channel

Public-key crypto basics

Pre-history of public-key crypto

- First invented in secret at GCHQ
- Proposed by Ralph Merkle for UC Berkeley grad. security class project
 - First attempt only barely practical
 - Professor didn't like it
- Merkle then found more sympathetic Stanford collaborators named Diffie and Hellman

Box and locks analogy

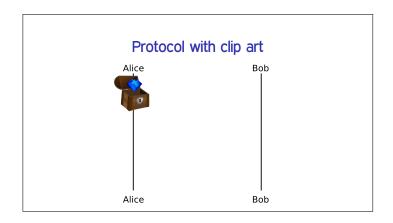

Alice wants to send Bob a gift in a locked box

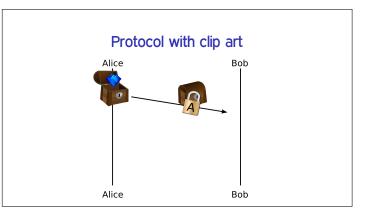

- They don't share a key
- Can't send key separately, don't trust UPS
- Box locked by Alice can't be opened by Bob, or vice-versa

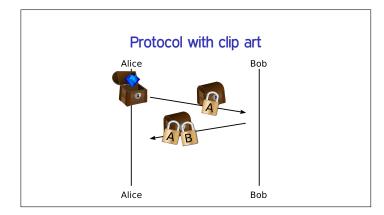

Box and locks analogy

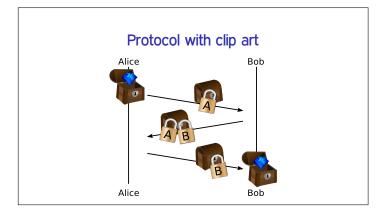

Alice wants to send Bob a gift in a locked box

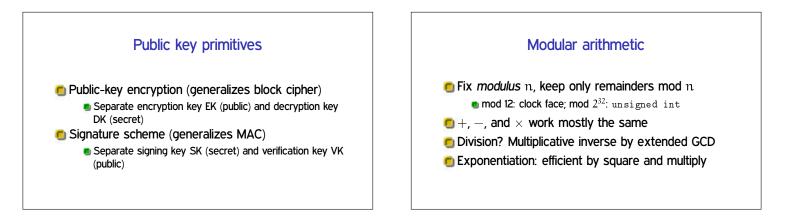

- They don't share a key
- Can't send key separately, don't trust UPS
- Box locked by Alice can't be opened by Bob, or vice-versa
- Math perspective: physical locks commute

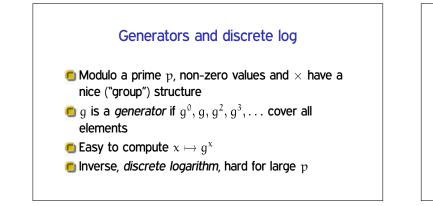

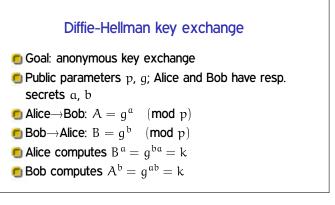

Relationship to a hard problem

We're not sure discrete log is hard (likely not even NP-complete), but it's been unsolved for a long time
 If discrete log is easy (e.g., in P), DH is insecure
 Converse might not be true: DH might have other problems

Categorizing assumptions

- Math assumptions unavoidable, but can categorize
- E.g., build more complex scheme, shows it's "as secure" as DH because it has the same underlying assumption
- Commonly "decisional" (DDH) and "computational" (CDH) variants

Key size, elliptic curves

- Need key sizes ~10 times larger then security level
 Attacks shown up to about 768 bits
 Elliptic curves: objects from higher math with
- analogous group structure (Only tenuously connected to ellipses)
- Elliptic curve algorithms have smaller keys, about 2× security level
