CSci 4271W Development of Secure Software Systems Day 20: Cryptography: public key Stephen McCamant University of Minnesota, Computer Science & Engineering

Outline

Building a secure channel

Announcements intermission

Public-key crypto basics

Good technical writing (pt. 1)

Public key encryption and signatures

Session keys

- Don't use your long term password, etc., directly as a key
- Instead, session key used for just one channel
- In modern practice, usually obtained with public-key crypto
- Separate keys for encryption and MACing

Order of operations

Encrypt and MAC ("in parallel")

 Safe only under extra assumptions on the MAC
 Encrypt then MAC

 Has cleanest formal safety proof
 MAC then Encrypt

MAC then Encrypt

- Preferred by FS&K for some practical reasons
- Can also be secure

Authenticated encryption modes

- Encrypting and MACing as separate steps is about twice as expensive as just encrypting
- "Authenticated encryption" modes do both at once
 Newer (circa 2000) innovation, many variants
- NIST-standardized and unpatented: Galois Counter Mode (GCM)

Ordering and message numbers

- Also don't want attacker to be able to replay or reorder messages
- Simple approach: prefix each message with counter
- Discard duplicate/out-of-order messages

Padding Padding oracle attack Adjust message size to match multiple of block size Have to be careful that decoding of padding does not leak information To be reversible, must sometimes make message longer E.g.: for 16-byte block, append either 1, or 2 2, or 3 3 3, up to 16 "16" bytes

Don't actually reinvent the wheel

- This is all implemented carefully in OpenSSL, SSH, etc.
- Good to understand it, but rarely sensible to reimplement it
- You'll probably miss at least one of decades' worth of attacks

Building a secure channel

Announcements intermission

- Public-key crypto basics
- Good technical writing (pt. 1)

Public key encryption and signatures

Pre-history of public-key crypto

First invented in secret at GCHQ

- Proposed by Ralph Merkle for UC Berkeley grad. security class project
 - First attempt only barely practical
 - Professor didn't like it
- Merkle then found more sympathetic Stanford collaborators named Diffie and Hellman

Box and locks analogy

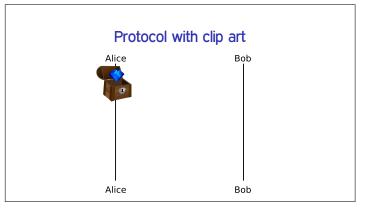

Alice wants to send Bob a gift in a locked box

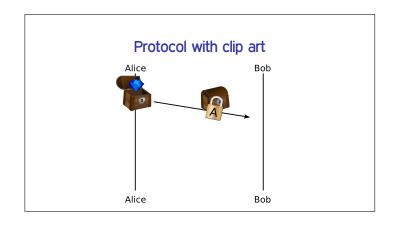

- They don't share a key
- Can't send key separately, don't trust UPS
- Box locked by Alice can't be opened by Bob, or vice-versa

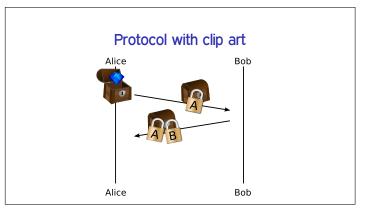

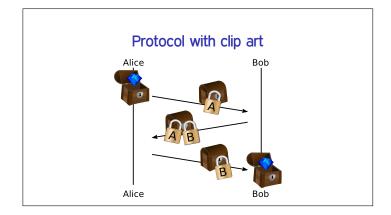

- Can't send key separately, don't trust UPS
- Box locked by Alice can't be opened by Bob, or vice-versa

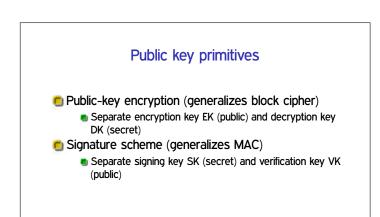

Math perspective: physical locks commute

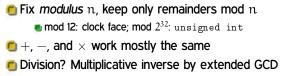

Modular arithmetic

Exponentiation: efficient by square and multiply

Generators and discrete log

- Modulo a prime p, non-zero values and × have a nice ("group") structure
- g is a generator if g⁰, g, g², g³, ... cover all elements
- **6** Easy to compute $x \mapsto g^x$
- 🖲 Inverse, *discrete logarithm*, hard for large p

Diffie-Hellman key exchange

- 🖲 Goal: anonymous key exchange
- Public parameters p, g; Alice and Bob have resp. secrets a, b
- $\textcircled{\bullet} \text{Bob} {\rightarrow} \text{Alice: } B = g^b \pmod{p}$
- **Solution** Alice computes $B^a = g^{ba} = k$
- **bob** computes $A^b = g^{ab} = k$

Relationship to a hard problem

- We're not sure discrete log is hard (likely not even NP-complete), but it's been unsolved for a long time
- If discrete log is easy (e.g., in P), DH is insecure
- Converse might not be true: DH might have other problems

Categorizing assumptions

- Math assumptions unavoidable, but can categorize
- E.g., build more complex scheme, shows it's "as secure" as DH because it has the same underlying assumption
- Commonly "decisional" (DDH) and "computational" (CDH) variants

Key size, elliptic curves

- Need key sizes ~10 times larger then security level Attacks shown up to about 768 bits
- Elliptic curves: objects from higher math with analogous group structure (Only tenuously connected to ellipses)
- Elliptic curve algorithms have smaller keys, about 2× security level

Announcements intermission

Public-key crypto basics

Good technical writing (pt. 1)

Public key encryption and signatures

Writing in CS versus other writing

- Key goal is accurately conveying precise technical information
- More important: careful use of terminology, structured organization
- Less important: writer's personality, persuasion, appeals to emotion

Still important: concise expression

- Don't use long words or complicated expressions when simpler ones would convey the same meaning. Negative examples:
 - necessitate
 - 🖲 utilize
 - due to the fact that
- Beneficial for both clarity and style

Know your audience: terminology

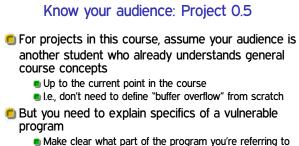

- When technical terminology makes your point clearly, use it
- Provide definitions if a concept might be new to many readers
 - Be careful to provide the right information in the definition
 Define at the first instead of a later use
- But, avoid introducing too many new terms Keep the same term when referring to the same concept

Precise explanations Don't say "we" do something when it's the computer that does it

- And avoid passive constructions
- Don't anthropomorphize (computers don't "know")
- Use singular by default so plural provides a
 - distinction:
 - The students take tests
 - + Each student takes a test
 - + Each student takes two tests

Provide structure

- Use plenty of sections and sub-sections
- It's OK to have some redundancy in previewing structure
- Limit each paragraph to one concept, and not too long
 - Start with a clear topic sentence
- Split long, complex sentences into separate ones

Explain all the specific details of a vulnerability

Inclusive language

- Avoid words and grammar that implies relevant people are male
- My opinion: avoid using he/him pronouns for unknown people
- Some possible alternatives
 - "he/she"
 - Alternating genders
 - Rewrite to plural and use "they" (may be less clear)
 - Singular "they" (least traditional, but spreading)

Public-key crypto basics

Good technical writing (pt. 1)

Public key encryption and signatures

RSA setup

- Choose n = pq, product of two large primes, as modulus
- n is public, but p and q are secret
- Compute encryption and decryption exponents e and d such that

 $M^{ed} = M \pmod{n}$

Output Decryption of C is $C^d = M^{ed} = M \pmod{n}$

RSA signature Signing key is (n, d) Signature of M is S = M^d (mod n) Verification key is (n, e) Check signature by S^e = M^{de} = M (mod n) Note: symmetry is a nice feature of RSA, not shared by other systems

Homomorphism

- Multiply RSA ciphertexts Multiply RSA ci
- applications
- Even more powerful: fully homomorphic encryption (e.g., both + and ×)
 - First demonstrated in 2009; still challenging

Problems with vanilla RSA

- Homomorphism leads to chosen-ciphertext attacks
- If message and e are both small compared to n, can compute M^{1/e} over the integers
- Many more complex attacks too

Hybrid encryption

- Public-key operations are slow
- In practice, use them just to set up symmetric session keys
- + Only pay RSA costs at setup time
- Breaks at either level are fatal

Padding, try #1

- Need to expand message (e.g., AES key) size to match modulus
- PKCS#1 v. 1.5 scheme: prepend 00 01 FF FF .. FF
- Surprising discovery (Bleichenbacher'98): allows adaptive chosen ciphertext attacks on SSL
 Variants recurred later (c.f. "ROBOT" 2018)

Modern "padding"

- Much more complicated encoding schemes using hashing, random salts, Feistel-like structures, etc.
- Common examples: OAEP for encryption, PSS for signing
- Progress driven largely by improvement in random oracle proofs

Simpler padding alternative

- "Key encapsulation mechanism" (KEM)
- For common case of public-key crypto used for symmetric-key setup

 Also applies to DH
- Hard to retrofit, RSA-KEM insecure if e and r reused with different n

Post-quantum cryptography One thing quantum computers would be good for is breaking crypto Square root speedup of general search Countermeasure: double symmetric security level Factoring and discrete log become poly-time DH, RSA, DSA, elliptic curves totally broken Totally new primitives needed (lattices, etc.) Not a problem yet, but getting ready

- Box and locks revisited
- Alice and Bob's box scheme fails if an intermediary can set up two sets of boxes
 - Middleperson (man-in-the-middle) attack
- Real world analogue: challenges of protocol design and public key distribution
