CSci 4271W Development of Secure Software Systems Day 21: Cryptography part 3 Stephen McCamant

University of Minnesota, Computer Science & Engineering

Outline

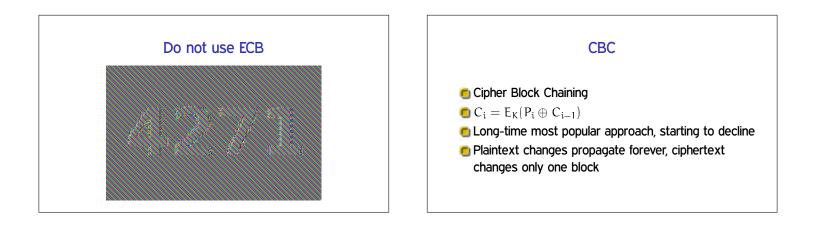

Block ciphers modes of operation Hash functions and MACs Announcements intermission Building a secure channel Public-key crypto basics Public key encryption and signatures

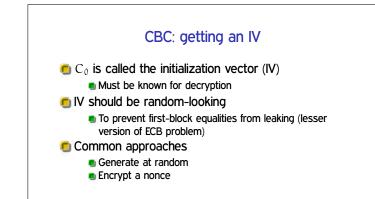

Modes of operation

- How to build a cipher for arbitrary-length data from a block cipher
- Many approaches considered
 - For some reason, most have three-letter acronyms
- More recently: properties susceptible to relative proof

ECB

- 🖲 Electronic CodeBook
- Split into blocks, apply cipher to each one individually
- Leaks equalities between plaintext blocks
- Almost never suitable for general use

Stream modes: OFB, CTR

- Output FeedBack: produce keystream by repeatedly encrypting the IV
 - Danger: collisions lead to repeated keystream
- Counter: produce from encryptions of an incrementing value
 - Recently becoming more popular: allows parallelization and random access

Outline

Block ciphers modes of operation

Hash functions and MACs

Announcements intermission

- Building a secure channel
- Public-key crypto basics
- Public key encryption and signatures

Ideal model

- Ideal crypto hash function: pseudorandom function
 Arbitrary input, fixed-size output
- Simplest kind of elf in box, theoretically very convenient
- But large gap with real systems: better practice is to target particular properties

Kinds of attacks

- **O** Pre-image, "inversion": given y, find x such that H(x) = y
- Second preimage, targeted collision: given x, H(x), find $x' \neq x$ such that H(x') = H(x)
- **(Free)** collision: find x_1 , x_2 such that $H(x_1) = H(x_2)$

Birthday paradox and attack

There are almost certainly two people in this class with the same birthday

o n people have $\binom{n}{2} = \Theta(n^2)$ pairs

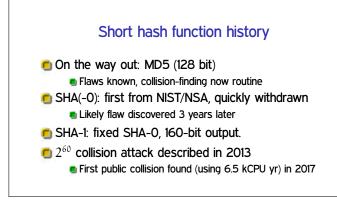

- **So only about** \sqrt{n} expected for collision
- "Birthday attack" finds collisions in any function

Security levels

- For function with k-bit output:
- Preimage and second preimage should have complexity 2^k
- Collision has complexity 2^{k/2}
- Conservative: use hash function twice as big as block cipher key
 - Though if you're paranoid, cipher blocks can repeat too

Non-cryptographic hash functions

- The ones you probably use for hash tables
- CRCs, checksums
- Output too small, but also not resistant to attack
- E.g., CRC is linear and algebraically nice

Length extension problem

- MD5, SHA1, etc., computed left to right over blocks
- **Or Can sometimes compute** $H(a \parallel b)$ in terms of H(a)
 - means bit string concatenation
- Makes many PRF-style constructions insecure

- SHA-2: evolutionary, larger, improvement of SHA-1
 - Exists as SHA-{224, 256, 384, 512}
 - But still has length-extension problem
- 5 SHA-3: chosen recently in open competition like AES
 - Formerly known as Keccak, official standard Aug. 2015
 - New design, fixes length extension
 - Adoption has been gradual

MAC: basic idea

- Message authentication code: similar to hash function, but with a key
- Adversary without key cannot forge MACs
- Strong definition: adversary cannot forge anything, even given chosen-message MACs on other messages

CBC-MAC construction

Same process as CBC encryption, but:

- Start with IV of 0
- Return only the last ciphertext block
- Both these conditions needed for security
- For fixed-length messages (only), as secure as the block cipher

HMAC construction

Project 1 submission 2 extended

New deadline: next Wednesday 4/13, 11:59pm
 One-time extension will be until Friday night
 My comments will be finished by Friday
 Visible gradually as they are posted

Block ciphers modes of operation

Hash functions and MACs

Announcements intermission

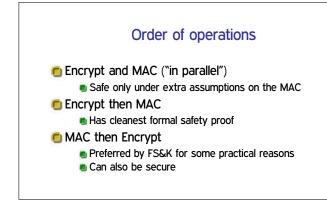

Building a secure channel

Public-key crypto basics

Public key encryption and signatures

Session keys

- Don't use your long term password, etc., directly as a key
- Instead, session key used for just one channel
- In modern practice, usually obtained with public-key crypto
- Separate keys for encryption and MACing

Authenticated encryption modes

- Encrypting and MACing as separate steps is about twice as expensive as just encrypting
- "Authenticated encryption" modes do both at once
 Newer (circa 2000) innovation, many variants
- NIST-standardized and unpatented: Galois Counter Mode (GCM)

Ordering and message numbers

- Also don't want attacker to be able to replay or reorder messages
- Simple approach: prefix each message with counter
- Discard duplicate/out-of-order messages

Padding

- Adjust message size to match multiple of block size
- To be reversible, must sometimes make message longer
- E.g.: for 16-byte block, append either 1, or 2 2, or 3 3 3, up to 16 "16" bytes

Padding oracle attack

- Have to be careful that decoding of padding does not leak information
- E.g., spend same amount of time MACing and checking padding whether or not padding is right
- Remote timing attack against CBC TLS published 2013

Don't actually reinvent the wheel

- This is all implemented carefully in OpenSSL, SSH, etc.
- Good to understand it, but rarely sensible to reimplement it
- You'll probably miss at least one of decades' worth of attacks

Outline

Block ciphers modes of operation

- Hash functions and MACs
- Announcements intermission

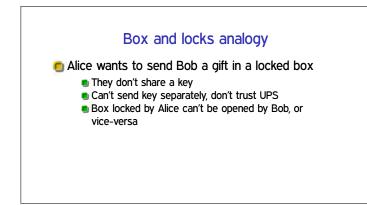

Building a secure channel

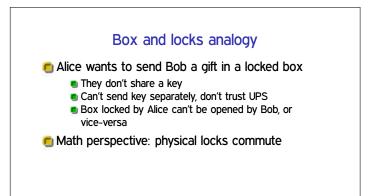

Public-key crypto basics

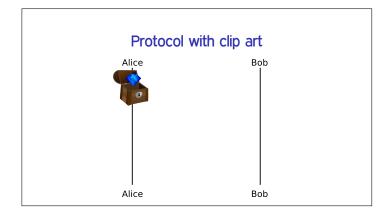

Public key encryption and signatures

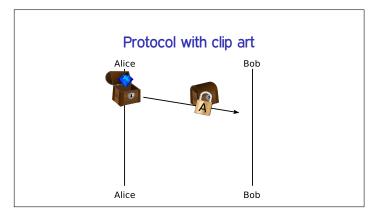

Pre-history of public-key crypto

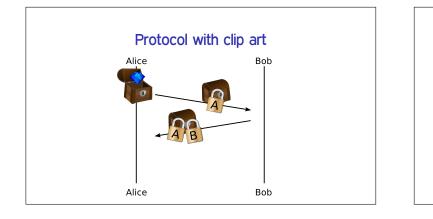

- First invented in secret at GCHQ
- Proposed by Ralph Merkle for UC Berkeley grad. security class project
 - First attempt only barely practical
 - Professor didn't like it
- Merkle then found more sympathetic Stanford collaborators named Diffie and Hellman

Public key primitives

Separate encryption key EK (public) and decryption key

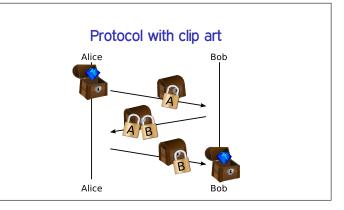

Separate signing key SK (secret) and verification key VK

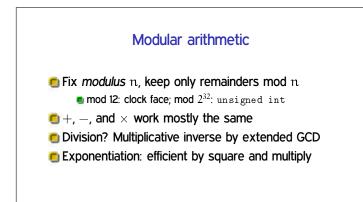

Public-key encryption (generalizes block cipher)

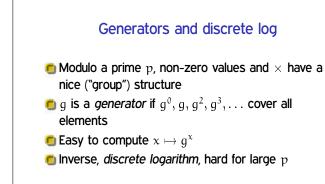

Signature scheme (generalizes MAC)

DK (secret)

(public)

Diffie-Hellman key exchange

- 🖲 Goal: anonymous key exchange
- Public parameters p, g; Alice and Bob have resp. secrets a, b

- Solution Alice computes $B^a = g^{ba} = k$
- **Solution** Bob computes $A^b = g^{ab} = k$

Relationship to a hard problem

- We're not sure discrete log is hard (likely not even NP-complete), but it's been unsolved for a long time
- If discrete log is easy (e.g., in P), DH is insecure
- Converse might not be true: DH might have other problems

Categorizing assumptions

- 🖲 Math assumptions unavoidable, but can categorize
- E.g., build more complex scheme, shows it's "as secure" as DH because it has the same underlying assumption
- Commonly "decisional" (DDH) and "computational" (CDH) variants

Key size, elliptic curves

- Need key sizes ~10 times larger then security level
 Attacks shown up to about 768 bits
 Elliptic curves: objects from higher math with analogous group structure
 - (Only tenuously connected to ellipses)
- Elliptic curve algorithms have smaller keys, about 2× security level

Outline

Block ciphers modes of operation Hash functions and MACs Announcements intermission Building a secure channel Public-key crypto basics

Public key encryption and signatures

General description

Public-key encryption (generalizes block cipher) Separate encryption key EK (public) and decryption key DK (secret)

- Signature scheme (generalizes MAC)
 - Separate signing key SK (secret) and verification key VK (public)

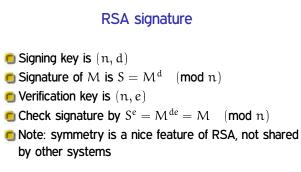

RSA setup

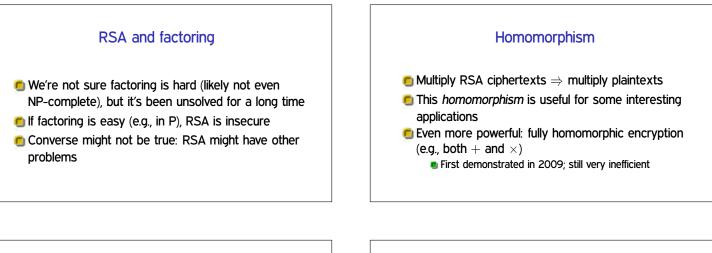

- $\ \, \hbox{ Choose } n = pq, \ \, \hbox{product of two large primes, as } \\ \ \, \hbox{modulus}$
- **on is public, but** p **and** q **are secret**
- Compute encryption and decryption exponents e and d such that

$$M^{ed} = M \pmod{n}$$

Public key is (n, e)
Encryption of M is C = M^e (mod n)
Private key is (n, d)
Decryption of C is C^d = M^{ed} = M (mod n)

Homomorphism leads to chosen-ciphertext attacks
 If message and *e* are both small compared to n, can compute M^{1/e} over the integers

Many more complex attacks too

Hybrid encryption

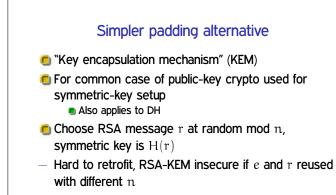

- Public-key operations are slow
- In practice, use them just to set up symmetric session keys
- + Only pay RSA costs at setup time
- Breaks at either level are fatal

Padding, try #1 Need to expand message (e.g., AES key) size to match modulus PKCS#1 v. 1.5 scheme: prepend 00 01 FF FF ... FF

Surprising discovery (Bleichenbacher'98): allows adaptive chosen ciphertext attacks on SSL Variants recurred later (c.f. "ROBOT" 2018)

Modern "padding"

- Much more complicated encoding schemes using hashing, random salts, Feistel-like structures, etc.
- Common examples: OAEP for encryption, PSS for signing
- Progress driven largely by improvement in random oracle proofs

Post-quantum cryptography

- One thing quantum computers would be good for is breaking crypto
- Square root speedup of general search Countermeasure: double symmetric security level
- Factoring and discrete log become poly-time
 DH, RSA, DSA, elliptic curves totally broken
 - Totally new primitives needed (lattices, etc.)
- Not a problem yet, but getting ready

Box and locks revisited

- Alice and Bob's box scheme fails if an intermediary can set up two sets of boxes
 Middleperson (man-in-the-middle) attack
- Real world analogue: challenges of protocol design and public key distribution
